ANALYSIS AND COST OF READY-TO-SERVE FOODS

AN INTRODUCTION BY

GRAHAM LUSK, Ph.D., Sc.D.*
Professor of Physiology of the Cornell University Medical College, and Scientific Director of the Russell Sage Institute of Pathology
NEW YORK

Very early in his scientific career, in the year 1877, Atwater turned his attention to the question of the nutrition of the people. The many valuable bulletins published by the United States Department of Agriculture testify to much splendid study into the problems of food for the multitude. And yet little practical use has come of it all. Why then talk about nutrition? A critic writes, "We need food, but do we need books to remind us of our need? And as an unanswerable challenge another critic cries, "Does Professor X eat his own diet?" It is truly stated that normal nutrition is associated with appetite, and it is therefore argued that the appetite is not to be controlled by knowledge. One has only to recall the appetite for drink to realize the utter fallacy of this argument. A glass of beer or a glass of wine taken at the end of a wearisome day is not of demonstrable evil and may be of benefit to the digestion. Yet to follow the appetite when it leads to drink in excess is of injury to the body, the mind and the economic welfare of the individual and therefore inimical to the welfare of the state.

But why repeat such self-evident truths? Has not enough been said? Are not words wasted in repetition of the obvious? In defense one may recall a scene at the New York Academy of Medicine in which Sir William Osler maintained that the essence of successful teaching consisted in "Reiteration, reiteration, reiteration." One of the audience present qualified this definition by adding the words, "without irritation." If successful teaching be accepted as "reiteration without irritation," let the following presentation be an attempt in that direction.

Food has been defined as a well-tasting mixture of foodstuffs of such a composition that the body is not injured by its use, and of sufficient quantity to maintain the body in good condition.

One may consider this definition under three headings.

1. Value of flavor.
2. Importance of composition.
3. Importance of quantity.

VALUE OF FLAVOR

It is known to all that the sight of appetizing food "makes the mouth water." It is known, however, to comparatively few that the sight of such food "makes the stomach water" in the same sense. That is to say, a flow of gastric juice is set up in the stomach. This flow is accelerated by the actual taste of the food, so that a large amount of valuable digestive fluid is set to flowing merely through the psychic appreciation of flavor. When food is taken without appetite, this important preliminary flow of gastric juice does not take place and proper digestion is rendered more difficult. Not only this, but the glands lying deeper down in the intestines yield their digestive juices in larger measure, the greater the quantity of gastric juice which passes from the stomach into the intestine. The appetite is like a magic wand influencing the whole of the digestive process. Fear and anger lead to a parched throat, and in an entirely similar manner to a parched stomach, so that food cannot be well digested under these circumstances. It is familiar to all that the sight, smell or sound of anything repellant will cause loss of appetite. The writer has seen an artist faint when an operation of Dr. Carrel became the subject of a dinner conversation where men and women were present. The appetite is favored by the extraneous refinements of civilized life, such as a spotless table cloth. It would also be affected by the cleanliness of the preparation of the food could one always look behind the scenes. It is affected by the atmosphere of cheer at the table. Neither scolding parents nor snarling children facilitate the digestion of the Christmas dinner.

The question of flavor in all its ramifications is therefore a very important one. It is one of the pitfalls of the prescribing physician, because he is very likely to believe that what he likes is excellent and what he detests is bad. The great multitude of people like pickles, but some do not; the latter class must not argue that pickles are therefore injurious. The common foods of life, such as potatoes, tomatoes, and bananas, all have their personal enemies based on dietetic prejudices which are largely imaginary, although as a psychosis the manifestations of repulsion are very real.

IMPORTANCE OF COMPOSITION

A celebrated school mistress once asked that a book be written which would tell her what apple sauce was without introducing the terms protein, carbohydrate and fat. Alas, that is impossible. It would be like teaching architecture without mentioning brick, granite and marble!

But the knowledge is not recondite. Protein is the characteristic solid constituent of muscle. The protein framework is essential for the manifestation of those properties whose aggregate is called life. And besides this, water and salts enter into the organization of the living particles. These salts are as varied as are those of the sea water and they are essential to living things. In vertebrates, salts are further used to build the larger framework of the bones. When *various molecules of protein are united in a certain* definite order with water and salts, life is possible. If the definite order is disturbed, death results. Life depends on the arrangement of the particles. One *recalls the story of the Yankee who, during the win*ter months, sold a "sure cure for potato bugs" with the caution "not to be opened till wanted for use" and with the promise of instructions for use inside the package. In the summer time, on opening the package the farmer found two small cubes with the directions "place the potato bug on one cube and press *firmly with the other." Death not only takes place* through such disarrangement of the particles, but also it may follow on the influence of a poison which pre*vents the proper functioning of the living thing.*

---

* This is the introductory to a report of an investigation of the ready-to-serve foods in the Childs restaurants of New York, by F. C. Gephart, Chemist of the Russell Sage Institute of Pathology, in affiliation with the Second Medical Division of Bellevue Hospital. The complete report, in book form, with Professor Lusk's introduction, may be obtained of the American Medical Association, price, ten cents; postage two cents extra.

A peculiarity of living tissue is that a part of its protein is constantly being broken down and replaced by repairing material. It is as if structural units were *constantly being dissolved out of a building and auto*matically replaced by new ones. In the human body about two and one-half parts out of a thousand of its protein are thus daily renewed. It is as if one structural unit out of every four hundred in a building were replaced with a new one every day. For this *reason one must eat protein.* This is repair protein to replace that lost in the wear and tear on the machinery of the cells.

Protein is the essential constituent of all meats, fish and eggs; it is a large constituent of milk, and mixed with fat is the essential constituent of cheese. Protein is not a simple chemical substance, but it may be broken into seventeen different fragments. This is what happens when protein is digested in the stomach and intestines. These fragments are absorbed by the *circulating blood and when they are carried to the* different tissues the fragments are put together in a manner which is characteristic for each tissue. Suppose each structural unit in a building were made up of seventeen parts, all of them different, such as gold, silver, iron, lead, tin and so on, and when one of these larger structural units went into the scrap heap suppose there were always present a supply of all the several varieties of new parts necessary to build another like it; then one has an analogy of what happens. *One might imagine that these seventeen differ*ent units might be arranged in different ways, depending on the use to which the particular structural unit was put. In like manner, it comes to pass that the protein of milk is split into fragments in the baby's stomach and these various fragments are absorbed by the blood and are carried by this medium to the different organs of the baby's body, there to build up the structure of each particular organ after its own particular way. The seventeen different chemical units known to occur in protein may be joined together in different ways so that 350 million times a million different combinations are possible even though only a single representative of each unit is used (Abderhalden). In this they resemble the multiplicity of combinations possible with the letters of the alphabet. On account of this it is possible to build liver protein or muscle protein out of milk protein. In the muscles of fish and in the white of egg there are again other *variations in the order of those letters of the* protein alphabet, and therefore, these proteins are distinctive. These proteins contain all the seventeen units and are therefore capable of repairing any tissue. It has been *suggested that such proteins be called* proteins of Grade A.

Proteins are also found in all vegetable foods. The vegetables contain some complete proteins, that is, *those which have the full array of seventeen individual* units, but they also contain some incomplete proteins, *that is, those which are deficient in one or more of* the characteristic units which are necessary to build *up animal protein. These incomplete proteins have* little or no value in nutrition. Thus it comes about that it requires a much larger quantity of vegetable proteins (which include complete and deficient proteins) *to maintain the machinery of the body in repair,* *than when animal protein is given in the form of meat,* eggs, fish, milk or cheese.

It must be remembered, however, that when a person is engaged in active labor or excessive exercise he may be able to obtain a very liberal supply of proteins of the higher grade in the large quantity of vegetable foods of which he partakes. This gives a scientific explanation to the saying which has become proverbial, "the railways of the country have been built on beans."

Attention is called to the generally overlooked value of milk protein.

There is no danger of protein undernutrition in this country. The general trend is toward protein extravagance, that is, its ingestion and destruction in excess of the needs of repairing the tissues. This is due to the fact that to most normal men a beefsteak represents the choicest of good things. Here appetite triumphs over reason and economy. If one listens attentively one hears again a rumbling note, "Would Professor X eat his own diet?"

Yet the matter of enormous meat consumption is one of serious economic importance which is not to *be lightly tossed aside. The following table prepared* by Rubner indicates the quantity of meat consumed per head of population (adults and children) in the various nations of Europe and also the increase in the consumption of meat in Germany during the last hundred years.

TABLE 1.—RUBNER'S TABLE OF MEAT CONSUMPTION IN EUROPE

	Present Consumption of Meat Per Capita Per Year, Pounds	Consumption of Meat in Germany in Different Years	
		Date	Pounds
Germany	115	1912	115
England	105	1900	102
France	74		
Belgium and Holland	75	1892	72
Austria-Hungary	64	1873	65
Russia	59	1840	48
Italy	23	1816	30

There is little doubt that excessive consumption of meat constitutes a grave and unnecessary economic waste. The increased cost of food falls most heavily on this item of indulgence and its ever-increasing price follows as much the law of supply and demand as does the price of champagne, and, for the same reason, the price of flavor for those who have the price. It is part of the spirit that demands the motor car, the luxuries of life as well as its necessities.

As regards the utility of carbohydrate and fat in the food, one may especially attribute to them a value as fuel. They are oxidized in the body and keep the body warm and when work is accomplished they furnish the energy with which to perform it.

The carbohydrates consist in sugars and starches. The latter are convertible into sugars in intestinal digestion. One can speak of cornstarch as equivalent to the sugar into which it is convertible. Cane sugar has essentially the same value in nutrition as starch. The two belong to the same group and yet are not identical, and so the layman must learn the cumbersome term carbohydrate as the common name for the physiologically identical sugars and starches.

The great staple starchy foods include rice, potatoes, bread, beans, macaroni and corn. These are the cheapest food fuels. They all contain protein but their principal constituent is starch, which when converted into sugar is as much a fuel for the body as gasoline is for the automobile.

Fat is taken in the food with most meats. It is largely consumed as lard and also as butter. Nuts contain 50 per cent. of their weight as fat. The fats are a far more costly fuel than the carbohydrates, although they serve a similar purpose in nutrition. The advantage of taking a diet which includes a mixture of carbohydrates and fats lies in the fact that the intestine is not called to excessive effort in caring for the digestion and absorption of a large quantity of a single food material, and that equivalent amounts of fat are less bulky than carbohydrates. The disadvantages of a large use of fat are, first, its original cost, and, second, the fact that its ingestion diminishes the intake of vegetables and hence the amount of cheap vegetable proteins, thereby making fat indirectly a still more expensive food.

There are important accessory factors to be discussed concerning food. These are the fibrous roughage of cellulose, the salts of the diet and the so-called vitamins.

Sylvester Graham used unbolted wheat flour with which to make Graham bread. The cellulose here produces a freer movement of the bowels. Of similar import is the use of spinach, cauliflower, lettuce, cabbage, asparagus and tomatoes. These substances have almost no fuel value, but they can be prepared to serve with large quantities of fats or oils, and they furthermore give flavor and variety to the fare of the table.

The salts of the food are extremely important. Thus, if calcium be withheld from the diet of experimental animals the bones become porous and finally break. Such conditions are not found in human life, for the foods ingested always contain sufficient salts to replace those lost from the body. It has been found that when meats are oxidized they yield an acid ash, whereas vegetables usually yield an alkaline ash. It has been recently shown by Blatherwick that of all vegetables potatoes yield the greatest amount of alkaline ash for the use of the body, and that this alkali is most effective in dissolving and eliminating uric acid from the system. In the light of this, potatoes are highly desirable, not only in health, but also in the gouty condition. Yet one of the dietetic fads of the day is to eliminate potatoes from the bill of fare, a really absurd practice, always excepting the cases of those individuals who manifest personal repugnance to potatoes.

Finally, there is a class of substances which exists in minute quantities in some foods and little or not at all in others. This class is called that of the vitamins. Thus, individuals who live almost exclusively on polished rice acquire the disease of beriberi, and a similar monotonous diet of bread develops scurvy. A diet of bread and water does not maintain the strength of the organism and has been used as a disciplinary method. Minute quantities of vitamins are found, for example, in meat, in butter and in unpolished rice, but they are absent or deficient in polished rice, bread and lard. The vitamins are absolutely necessary for the proper harmonious maintenance and growth of the body. This statement should cause no alarm. There is no beriberi in the United States, for here rice does not ever form the dietary mainstay of the individual. There is practically no scurvy, although it has been known to occur in almshouses, where motives either of economy or graft have deprived the inmates of suitable food.

Summarizing, one can state that in the United States there is no protein, or salt or vitamin deficiency in the habitual diet, and there is plenty of roughage in the form of cabbage, sauerkraut or other vegetable foods available to him who desires it.

THE QUANTITY OF FOOD

Generally speaking, the mass of food ingested serves two functions, the protein is of use in the maintenance and repair of the cell machinery, and the carbohydrate and fat furnish fuel to this machinery that the motions of life may continue. Protein given in excess also serves the purpose of fuel, as do carbohydrates and fat. In the oxidative destruction of these materials in the body heat is liberated. When 1 gram of fat is burned sufficient heat is produced to raise the temperature of 1 liter of water 9.3° C. (= 16.5° F.). Since the unit of heat measurement or the *calory* is that quantity of heat required to raise 1 liter of water 1° C., it follows that 9.3 calories of heat are set free whenever 1 gram of fat is oxidized. The heat liberated in the body when 1 gram of fat is oxidized is exactly the same as when it burns outside the body. The similar value for starch is 4.1 calories per gram. In the case of protein, 4.1 calories are liberated whenever a gram of this material is oxidized within the organism. When, therefore, protein is consumed in excess, the excess has no greater fuel value than an equal weight of starch. Here then are the fuel resources which keep the body warm, maintain the heart and respiration, and the activity of the other organs, and enable the muscles to perform work. Since every machine requires more fuel when it is active than when it is at rest, it follows that the greater the activity of the body the greater will be the requirement for fuel.

The figures in Table 2 may be accepted as estimates of the fuel requirement of a man weighing 156 pounds (70 kilograms) during a twenty-four-hour period:[1]

TABLE 2.—DAILY CALORIC REQUIREMENTS OF 156 POUND (70 K.) MAN

	Calories
Absolute rest in bed without food	1,680
Absolute rest in bed with food	1,840
Rest in bed 8 hours, sitting in a chair 16 hours, with food	2,168
Rest in bed 8 hours, sitting in a chair 14 hours, walking two hours, with food	2,488
Rest in bed 8 hours, sitting in a chair 14 hours, vigorous exercise 2 hours, with food	2,982

---

[1] Lusk: The Fundamental Basis of Nutrition, Yale University Press, 1914.

It appears from this that that great class of human beings whose business it is to sit at their desks or to watch machinery, and who may walk to and from their work, require 2,500 calories. In their class are included writers, draughtsmen, tailors, physicians and other professional men, clerks, accountants, etc. Mental effort is accomplished without any increase in the quantity of energy required.

Individuals who stand at their work, such as bakers, dentists, car conductors, decorators and glass workers, require about 3,000 calories. If muscular labor be constant, more is required. Thus carpenters making tables and painters painting furniture require 3,300 calories. Farmers require 3,500 calories, stone masons 4,500, lumbermen 5,000 and over, and a man riding in a bicycle race during twenty-three hours requires 10,000 calories a day.

These are facts which at the present time are scarcely open to dispute. The sorrowful part of it is that outside a narrow circle they are practically unknown. Physicians sometimes starve their patients and the babies entrusted to their care, in blissful and childlike ignorance of what they are doing. The poor, 50 to 60 per cent. of whose income is spent for food, waste their money in the purchase of beautiful labels or relatively expensive and unnutritious foods. A publisher employing several thousand individuals says that his employees buy from choice the products advertised in his magazines. Children of the poor are sent to buy food for the family and the whole expenditure of half the family's income is effected in an atmosphere of unfathomable ignorance. Yet if one seeks to help, one is informed that one must not meddle with the appetites, and the funny man of the newspaper makes a witticism on the subject of "highbrow" information.

In spite of the inevitable attitude of the humorous editor, it is well to remember the severity of the winter's cold, the lack of employment, the suffering of the poor, which create a situation very far from humorous.

How can relief be given? One suggestion is to sell 1,000 calories of food in a well-balanced ration as cheaply as possible. Beans are cheap. But you don't like beans. Does Professor X eat his own diet? If beans are not acceptable, then how about macaroni and spaghetti? The meal shown in Table 3 is made up of 1,000 calories and contains 16 per cent. of those calories in protein, one-sixth of the protein being in the form of animal proteins of Grade A, and the rest being in vegetable proteins. The remaining 84 per cent. of the calories are nearly equally divided between carbohydrate and fat.

TABLE 3.—COMPOSITION OF A RATION CONTAINING 1,000 CALORIES

	Ounces	Calories
Cooked beans	7⅜	400
Pork	1	234
Bread	2⅓	180
Butter	½	103
Milk	5	100
Coffee	5	...
Total		1,017

The actual cost price of this meal of hot pork and beans, bread and butter and a cup of hot coffee and milk is 4¼ cents, excluding labor and rent, but including the coal used. The 2,500 calories required to maintain a man out of work on this diet would cost

TABLE 4.—THE COST OF 2,500 CALORIES IN FOODS ARRANGED IN ORDER OF THEIR INCREASING PRICE

Note that when three portions furnish 2,500 calories, one portion affords a good meal. When nine portions furnish 2,500 calories, then three different portions should form the meal.

Name of Food	Nutritional Calories for Five Cents	Per Cent. in Bread and Butter	Cost of 2,500 Calories	No. of Orders to Make 2,500 Cal.
Napoleon	453.6	....	$0.28	6

† Not purchased in the restaurant.

10.6 cents a day, or $38.70 a year. If such a thing as a "submerged tenth" really exists in this country it would cost $387,000,000 to feed 10,000,000 men for one year on this diet. The taxation in the United States, city, state and national, is said to be $4,000,000,000 annually. Ten per cent. of this sum would feed with pork and beans, bread and butter, coffee and milk, 10,000,000 men who are out of work. A similar menu just as cheap can be based on spaghetti flavored with tomato or cheese. It is not argued that a diet based on the cheaper foods is a panacea for all the woes of the world. It is not argued that such diets are the equivalent of caviar, champagne and canvas back ducks, but it is argued that good wholesome simple food should be more available for mankind at a moderate price in hours of adversity and distress than is the case to-day. People should know how they can conserve their resources without detriment to their bodily welfare.

Passing to the consideration of the nutrition of the great mass of the people it seems probable that at the present time no more valuable data can be obtained than those which may be derived from a study of the various food portions solds by the Childs restaurant establishments which are situated in many cities throughout the country. The portions served are standardized, i. e., planned to be uniform in quantity and quality and the prices are the same in all the restaurants. Mr. F. C. Gephart has completed a notable analysis of 350 different portions as they are sold to guests at these establishments. The results of these analyses have been tabulated. Table 4 gives the cost of each food if that particular variety were alone made to furnish the 2,500 calories necessary for a man leading a sedentary life, to which is added the restaurant price of these 2,500 calories and the number of portions necessary to furnish them. Portions which contain 15 per cent. of protein calories or more have received a star. Portions which contain meat, fish, egg or milk proteins are preceded with the letter A, indicating the presence of animal proteins. The material in this table is arranged in the order of the increasing price of the food.

It appears that fourteen different orders yield enough food fuel for one day at a cost of less than 40 cents, or less than $145 per annum. Of these the roast beef sandwich made as a roll is conspicuous for cheapness.

Thirty-three different portions may yield the total energy requirement of 2,500 calories at a cost of less than 50 cents per day.

Suppose a restaurant be established with these thirty-three varieties only, and the consumer arranged his dietary so that he paid an average price of 40 cents for 2,500 calories, it would cost him $145 per annum for his food. If it be a fair division of one's income to expend one-fourth for rent, one-fourth for clothes, one-fourth for food and one-fourth for extras, then a single man may live at a Childs restaurant when his income is $50 a month, of which he spends $12.50 for food if he restricts himself to those thirty-three varieties. As a married man he would require $100 a month to maintain himself and his wife under similar circumstances.

Passing to food of a higher cost, it appears that thirty-two portions yield 2,500 calories at a cost of between 51 and 60 cents and here portions containing meat predominate.

There are forty-two varieties of foods which yield 2,500 calories between 61 and 70 cents and thirty-three which cost between 71 and 80 cents. At this latter level of cost orders for eggs such as fried eggs and creamed eggs on toast begin to appear.

Twenty varieties yield 2,500 calories at a cost of between 81 and 90 cents and twenty-four varieties cost between 91 cents and $1.00. The sirloin steak appears at the level of 91 cents.

This gives a choice of 184 dishes which yield 2,500 calories at a maximum daily cost of $1.00.

There are fifty-five varieties of food which cost more than $1.00 per 2,500 calories. The cost rises rapidly. Seven orders of two boiled eggs (with but-

TABLE 5.—*Continued*

SUMMARY	Cost in Cents	Cal-ories
Monday	40	2,655
Tuesday	60	2,712
Wednesday	55	2,453
Thursday	55	2,618
Friday	55	2,810
Saturday	55	2,630
Sunday	70	3,236
Per week	$ 3.90	19,174
Per diem	0.56	2,739
Per month	16.80	

Individual income appropriate to this expenditure is $67.20 per month.

tered toast) costing $1.03 for 2,500 calories stand out in their extravagance, but this is outdone by nine orders of two poached eggs on toast costing $1.91 for the day's requirement. The portion of spaghetti with cheese is certainly overpriced, and were the service to an Italian clientele would not be so costly.

The greatest wonder appears in the cost of the tomato portions. Tomatoes with lettuce and dressing cost over $9.00 for 2,500 calories, nearly as much as cantaloupe at $10.00, while champagne (bought outside the restaurant at $4.00 a quart) costs $14.00 for 2,500 calories.

The mystery of tomatoes is baffling. A can of tomatoes is little else than flavored water. The popularity of the tomato probably depends on its flavor and its color. A painter wishing to sell a landscape puts a figure with a red cloak in the center. It is an ancient device. In like manner, a restaurant puts a few lettuce leaves on a plate with a red tomato in the middle, covers it with a little dressing and gets a large price. It is the work of an artist for a connoisseur.

To indicate the practical value to which this work may be put, the following selected menus have been arranged. They give the cost and caloric content of inexpensive dishes which may be ordered at the restaurant and which provide for three meals a day during a week for a man of average weight. Only the morning cup of coffee occurs more than once.

TABLE 6.—COST TABLE

Ham and Eggs, 25 Cents	Cents
2 Eggs	6.66
3½ oz. Ham	4.40
3 Slices bread	0.45
10 gm. Butter	0.89
2½ oz. Potatoes	0.04

3 Slices bread	0.45
10 gm. Butter	0.89
2½ oz. Potatoes	0.04
1,300 calories	18.68

Ham Sandwich, 5 Cents	Cents
½ oz. Ham	0.70
2 Slices bread	0.30
10 gm. Butter	0.89
200 calories	1.89

At Bellevue Hospital, New York, in 1912, the cost of food from the market, that is, of uncooked food, was 25 cents daily for 3,200 calories for each person in the establishment; at the Muncipal Lodging House during 1911 the cost was 13 cents daily for 2,700 calories per person.

When one considers that Childs restaurant pays for service and for expensive ground floor rental in the busiest parts of New York City, surely food at the cost outlined above is not expensive. But this menu is laboratory made, calculated from the scientific standpoint and from the standpoint of food economics. The restaurant in question could easily give this information on its menu card. It would have immense educational influence were it to do so.

In a few selected portions Mr. Gephart has estimated the retail market value of materials entering into the portions sold and these are revealed in Table 6.

It is evident that the actual cost of these standard portions is about half to one-third their cost in the restaurant. The housewife who knows how to buy the essential ingredients, and especially how to cook them, is an economic factor of prime importance in the home. Of such stuff is the science of food economics.

Mr. Gephart's work is the first extended investigation of its kind. It would be wise if the public could be better informed regarding the caloric value of foods which it purchases. It would be of vast significance if the barrel of flour, the can of lard, the pot of beans or the package of breakfast food could be labeled with the caloric content of the particular unit of sale.

The question would not then be asked, would Professor X eat his own diet? But the individual could then ask himself, am I sufficiently well-to-do to be careless of what I spend for food? And, can I spend less with equal profit and as great satisfaction?

SCOPOLAMIN-MORPHIN TREATMENT IN LABOR

A CRITICAL ANALYSIS OF SIXTY CASES

JOSEPH LOUIS BAER, S.M., M.D.
Associate Attending Obstetrician, Michael Reese Hospital
CHICAGO

A series of cases under scopolamin-morphin treatment was begun January 1, this year, in the Michael Reese Maternity, on the obstetric service of Dr. Lester E. Frankenthal, and continued on the service of Dr. Frank Cary. The series terminated February 5.

All private cases, all cases that threatened to become pathologic, and all cases that came in too soon before delivery to permit of the proper administration of the drugs, were kept out of the series. The total number analyzed was sixty.

Of the four delivery rooms in the Michael Reese Maternity, each constructed with cork-lined, soundproof walls and sound-proof doors, the largest was chosen for the "twilight sleep" cases. Two nurses, both graduates with extensive obstetric experience, were especially engaged for day and night duty during the entire period of the series, and they remained constantly in the delivery room. The patients were furthermore under the continual observation of either the senior or junior intern on obstetrics, and of the day and night head nurse in charge of the maternity. All results were tabulated and the observations were constantly checked by Drs. Frankenthal, Cary and myself.

Patients in labor were sent to the third floor admitting-room where they received a tub bath (sponge bath if membranes had ruptured), shaving of the genitals, and an enema, if not too far advanced in labor; when, if suitable for the series, they were taken to the delivery room, where treatment was begun with the following indications; in multiparas, when the pains recurred every ten minutes, and in primiparas when the pains recurred every five minutes.

The drug used in the earlier cases was a tablet form of scopolamin put out by Sharp and Dohme and made by Merck; later a powder form of scopolamin by Merck and ampules of scopolamin from Hoffman-LaRoche, preserved with mannite, according to the formula of Straub of Freiburg, were employed in alternate cases.

The total dosages varied from one-eighth to one-quarter grain morphin and from two doses of 1/200 to nine doses of 1/150 and eleven doses of 1/200 grain scopolamin, hypodermically. Subdued light, smoked glasses and avoidance of unnecessary and loud talking were strictly enforced. Observations on all points brought out in the literature were taken and recorded at half-hour intervals, and oftener when necessary.

The accompanying table represents a summary of the sixty cases in two groups, primiparas and multiparas. A few of the items were analyzed in only the last twenty-one cases, and are marked "2d S."

At the close in each case a brief impression of that case was written, and these remarks are here presented verbatim in groups arranged according to the degree of success or failure.

RESULTS OF TREATMENT

NO SUCCESS, TWENTY-SIX CASES

Case 10.—Patient's memory was clear at all times. Patient was somewhat indifferent to the pains, but said that the pains were severe.

Case 13.—Slight vertigo—memory clear at all times.

Case 29.—Patient's memory clear throughout, slight flush and marked thirst being the only noticeable symptoms.

Case 32.—At no time during labor had patient the slightest cloudiness of memory, sleeping between pains.

Case 53.—Patient was delirious for several hours, doing foolish stunts and was very restless.

Case 55.—Patient was very delirious, throwing herself about in a wild manner and later required restraint.

Case 56.—Very restless—the drug increased her restlessness.

Case 58.—Very restless, and during the second stage patient was absolutely unmanageable—could not be aroused and had to have restraining sheet.

Case 61.—Treatment stopped after 5/150 grain scopolamin and 2/8 grain morphin because labor pains ceased. Patient also vomited and became restless; fetal heart tones dropped to 96 and forceps were used.

Case 63.—Not much effect of the drug could be seen.

Case 66.—Patient had a mitral insufficiency and myocarditis, a supposedly ideal case for the use of the treatment. After three doses subcrepitant râles appeared in the upper left lung, the pulse became fast and irregular and the fetal head stood in deep transverse arrest. Forceps and immediate extraction were followed by a pulmonary edema, from which the patient finally recovered. The baby was born in asphyxia pallida and was resuscitated with difficulty.

Case 68.—No effect of drug noticed.

Case 3.—Patient's memory at all times was clear and no effect of the drug noticeable.

Case 9.—Patient's memory at all times was clear and very little effect of drug could be noticed. Patient had difficulty in getting the head past the outlet. Pains were strong, but no progress. "Kristeller" resulted in normal delivery.

Case 11.—Delivery rapid following a somewhat quiet period. Patient quite indifferent, apparently having little pain, but somewhat cyanotic.

Case 12.—Patient in the beginning was quiet; after the third dose became somewhat noisy and hysterical; memory was clear throughout labor.

Case 14.—Child revived with difficulty. Later condition good. Treatment did not give desired effect of drugs.

Case 19.—With heart tones at 108 from 124 after two doses, deemed it inadvisable to continue the treatment. Patient's mind was clear at all times and no effects of the treatment were noticeable.

Case 25.—Patient had no disturbance of memory.

Case 33.—Patient stopped for about four hours; after the fourth injection of scopolamin no effects of the drug were obtained.

Case 37.—Patient's memory was clear at all times.

Case 59.—Patient's memory clear throughout labor. After delivery became restless, then delirious, got out of bed and ran to window, getting onto the sill, was dragged off by the nurse, overpowered her, ran to the rear stairway, where three nurses finally succeeded in subduing her and getting her into the quiet room, where she was shackled and kept so four days, when she finally became entirely rational again.

Case 62.—Patient's memory clear throughout. Case terminated by rupture of uterus. Patient, nonipara, had three doses of scopolamin 1/200 grain, and 2/8 grain morphin. After the last dose at 1:45 a. m., pains became less frequent and stopped at 4:30 a. m. At this time the fetal heart tones could no longer be heard, and the patient gradually became semiconscious. At 6:30 she was pale, and sweat appeared on the brow. The dilated cervix was found collapsed and the presenting head had receded. Diagnosis, rupture of the uterus, seen by Drs. Frankenthal, Cary and myself, abdominal section done, fetus and placenta found free in the abdominal cavity, a jagged transverse rupture in the lower uterine segment of the uterus, running straight across the whole width anteriorly just at the level of the fundus of the bladder and a huge retroperitoneal hematoma up to the kidney. Hysterectomy was done—patient died on the second day.

Case 65.—No effect of drug noticed.

Case 67.—No effect of drug noticed.

Case 70.—No effect of drug noticed.

LITTLE SUCCESS, SEVEN CASES

Case 6.—Patient's memory seemed clear at all times, bearing down pains were very few.

Case 16.—Toward the end, patient appeared for a few seconds rather confused. Memory always clear, slightly irrational after returning to the ward, restless and required restraint.

Case 18.—Patient at no time before delivery had cloudy memory. Pain lessened toward end.

Case 20.—Labor seemed very easy, patient's memory was clear at all times.

Case 49.—With the exception of about two hours after the fourth dose, patient had clear memory throughout.

Case 69.—Patient slightly drowsy at birth, but knew of birth.

Case 7.—Patient's memory was slightly cloudy at time of birth.

PARTIAL SUCCESS, EIGHT CASES

Case 15.—Drugs apparently had some effect on memory though not throughout. Duration of effect rather short—no marked improvement on giving last dose; patient very noisy, excited, and at times toward the end became irrational and difficult to control until about the last hour, when she quieted down considerably.

Case 24.—Patient had six doses 1/150 grain of scopolamin, but had few symptoms showing effect; although patient responded to memory tests before birth she had no recollection of the birth of child. She says she had chloroform.

Case 28.—Amnesia present to slight degree. Patient very noisy during the last hour, and had to have restraining sheet in ward.

Case 34.—Patient appeared very drowsy. Difficult to concentrate thoughts. At intervals she seemed to have cloudy memory for events.

SUMMARY OF CASES

	Totals	Primiparas	Multiparas
Cases	60	33	27
Drugs:			
Scopolamin, total amount (range)	....	2/200-9/150-11/200	8/150-7/200
Morphin, total amount (range)	....	1/8-2/8	1/8-2/8
Time from first to last hypodermic (range)	....	1: 15-19: 45; Av., 8: 15	1: 15-12: 15; Av., 5: 35
Duration (Compared with an untreated series of one year ago):

CASE 17.—Toward the end patient seemed slightly confused. Memory occasionally cloudy, but was quite clear after delivery.

CASE 21.—Patient drowsy throughout from a half hour after the first injection. Attempted to sleep between pains. Pain apparently uninfluenced; memory clear throughout.

CASE 48.—Patient was under effect of the drugs only at the very end. Treatment lasted 6½ hours.

CASE 51.—Patient's memory was only slightly cloudy.

FAIR SUCCESS, FIVE CASES

CASE 8.—Patient's memory was clear throughout, but she appeared indifferent to what was going on.

CASE 43.—Patient was under influence of the drug as concerns amnesia for about one hour. Treatment lasted five hours and twenty-five minutes.

CASE 44.—Patient's memory was cloudy—excitation in the last half hour very marked, throwing herself about wildly. In the ward she had to be tied in bed.

CASE 45.—Patient was wildly delirious at time of pain, sleeping between pains, but throwing herself about for two hours before delivery in a wild manner.

CASE 57.—Postpartum hemorrhage half hour after patient returned to bed. Patient did not know when the baby was born. Abdominal muscles not used after the fifth dose of scopolamin.

GOOD SUCCESS, EIGHT CASES

CASE 5.—Patient seemed to come partially out of the effect of the treatment shortly before delivery.

CASE 22.—Patient after the first three doses showed considerable amnesia; partially recovered; after last two doses she showed amnesia again and doesn't remember when the baby was born.

CASE 26.—After the third dose did not use her abdominal muscles; hence head remained at the vulva longer than need have been.

CASE 35.—Memory tests were interfered with on account of the delirium present. Patient seemed to remember on the following morning much better than had been expected.

CASE 47.—Patient was very quiet; very difficult to arouse; memory was cloudy; abdominal muscles not acting.

CASE 40.—So far as could be ascertained, this case was a success; patient quite an ignorant person and information difficult to obtain; memory quite cloudy; pain not noticeably diminished.

CASE 41.—Patient quite noisy immediately prior to delivery, but after child was born she slept, during which motions of the extremities were spasmodic and involuntary. Drug seemed to act promptly, and amnesia was present after the second dose.

Case 54.—Amnesia attained at the time of delivery—temporary—semi-delirious toward the end.

COMPLETELY SUCCESSFUL, SIX CASES

CASE 23.—Patient had absolute loss of memory, but was very delirious, throwing herself about in a wild manner. Repair work was almost impossible on account of her wild actions, and restraint was necessary in bed. Child started breathing with little stimulation; ten minutes later stopped and artificial respiration had to be resorted to.

CASE 60.—Patient did not know when baby was born. Conduct during labor excellent.

CASE 42.—Patient's memory was only slightly cloudy prior to delivery, but amnesia was more marked after the birth of the child. Delivery was rapid.

CASE 46.—Patient was very quiet and slept all the time from one hour before delivery until several hours thereafter. Pains during second stage were good, regular and strong, but abdominal muscles were not used.

CASE 50.—Patient's memory was cloudy. Gave no expression of pain at time of birth and slept most of the time.

CASE 52.—Patient's amnesia was complete. Slept almost all the time, arousing only slightly at the return of each pain.

Two primiparas, cases 53 and 56, classified as unsuccessful, received the maximum total doses, 9/150 grain scopolamin, and a primipara, case 49, classified as slightly successful, received 11/200, whereas case 60, primipara, and cases 42, 46 and 50, multiparas, classified as completely successful, each received a total of only 3/150 grain scopolamin. These striking variations in dosage, effective conversely to the total amounts used, show clearly how utterly uncertain the outcome must be in any given case. But the women whose faith in their local physicians of worth has been shaken by the trumpet blasts of the optimists—what do they know about these petty details?

The average duration of the so-called first stage (17:10, primiparas, and 14:15, multiparas) exceeded that of a series of one year ago of the same number of cases taken for comparison (10:20, primiparas and 7:55, multiparas) by about seven hours, while the second stages in the two series (2:10, primiparas, and 1:59, multiparas, this series, and 2:00, primiparas, and 1:33, multiparas, untreated series) were about equal. However, it must be remembered that the total number of bimanual examinations made on the entire sixty cases was only seventy-seven, and that every patient admitted to the Michael Reese Maternity is examined once bimanually as soon as prepared after admission, and thereafter not again unless there is the strictest indication; hence the onset of the second stage had to be determined in most cases by other means, such as rupture of membranes, bearing down pains, etc., and as a result the seven hour retardation should be considered as applying to the combined first and second stages. To overcome this generally conceded prolongation of labor (though several writers have claimed the opposite result) pituitary extract has been freely and frequently employed elsewhere. Such juggling with the natural powers, like the combined use of the brake and the whip, has seemed to us an attempt to make a right out of two wrongs. The use of pituitary extract in the Michael Reese Maternity service is limited sharply to the terminal portion of the second stage, when its maximum benefits are seen without secondary disadvantages.

Memory tests were carried out conscientiously but without unnecessarily disturbing those patients that seemed somnolent. Twenty-six remained clear throughout labor, thirty-nine were cloudy, yet the twenty-six had a greater total of scopolamin than the thirty-nine.

Thirty-two women complained of a thirst so intense as to be literally unquenchable. Their parched mouths and incessant requests for water were not the least distressing feature of the treatment.

Headache and vertigo were present in twenty-seven and thirty-one cases, respectively, and the former was a source of much distress and even intense suffering, persisting for several days in some cases. Yet these same women who were rendered so wretched, in many instances for hours and days after delivery, would have gone through a normal confinement of from eight to eleven hours' average duration, and would have been comfortable and happy thereafter, if they had not had the so-called blessings of "twilight sleep."

Forty-three patients slept part of the time, but could always be easily aroused, seeming to respond to external stimuli and to feel the contractions.

Pain was felt by many of these women regardless of the number of doses of scopolamin. It was diminished in thirty-nine, absent in one, average in nineteen and increased in one. That this applied equally to the cases at Freiburg, is evidenced by the various series in which additional anesthetics were used at the end, such as ether, ethyl chlorid, etc. If this be so, then why discard the old and tried combination of morphin hypodermically for pain and chloral by rectum, with completely effaced and partially dilated cervix, as used by the obstetricians of the Michael Reese Maternity for more than a quarter of a century with safety? The typical analgesia and amnesia of the more favorable reports in the literature were obviously not attained in a large number of cases in which we had every reason to expect results if the claims made by the proponents of this procedure had been substantiated.

Restlessness was present in eighteen cases and delirium in nine, in seven of which restraint and shackling were necessary. These "obstetrical jags," as Dr. Cary so aptly put it, represented the most annoying and unpleasant phase of the whole investigation, appeared in every kind of case with few or many doses, and necessitated unremitting watchfulness on the part of the nursing staff and interns, in spite of which such incidents as those in Case 59 occurred.

The serious risk of self-infection during labor engendered by the uncontrolled motions of these women was a source of constant anxiety. They sat cross-legged and the heel would enter the vulva. In their vague efforts to reach the region of pain, they repeatedly attempted to explore their genitalia. It was next to impossible to keep the genitalia free from feces, and the fact that we had no infections can be ascribed chiefly to the careful initial preparation all patients receive in the admitting room of the maternity, plus the untiring alertness of the nursing force to keep these women from harming themselves. In this connection, comment is in order on the practice of one clinic, in which patients undergoing the treatment are virtually under strait-jacket restraint. Is a treatment necessitating such measures deserving of recognition, much less approbation?

Three days prior to the occurrence of Case 62, rupture of the uterus, Dr. Frankenthal spoke to me of the danger that this treatment could obscure such important symptoms as the pain in premature separation of the placenta, *cessation of pains* in rupture of the uterus, even the presence of an eclampsia suppressed by medication similar to the Stroganoff treatment; and though thanks to the day and night staff, this case was detected, who knows what further disasters might happen in future series or isolated cases, under the combined blanket of the drug, the semidarkness of the room and the patient too restless for proper examination?

Birth in all cases but four was spontaneous. Case 9, sextipara, Kristeller, after the head had been on the perineum one and one-half hours; Case 61, primipara, heart tones dropped to 96, after 27:10 hours of labor and low forceps were applied; Case 66, primipara, broken cardiac compensation, head in deep transverse arrest after 22:25 hours, 4:25 of which were in the hospital, terminated by forceps; and Case 62, abdominal section for rupture of the uterus.

Amnesia at birth was entirely absent in twenty-eight, present in twenty-six, and marked in five, while analgesia was present in four, slight in five, pain was average in thirty-seven, and marked in eight at birth. Ether was used in three cases, all operative.

Perineal tears occurred in twelve cases, or 20 per cent. of the series, seven in primiparas, and five in multiparas, ranging from slight first degree, to deep second degree, all of which were repaired immediately, this being the routine in the Michael Reese Maternity for all tears however slight. In the untreated series of sixty cases of a year ago there were seventeen perineal tears, or 28 per cent.; but in this connection it is debatable whether a very slow passage of the head over the perineum and through the vulva, leaving the mucocutaneous surfaces intact, to be sure, but causing a separation of the perineal musculature subcutaneously with subsequent rectocele and possible prolapse, is more desirable than an occasional episiotomy with immediate and accurate repair. The understanding women of this generation seem much more concerned lest a tear be left unsutured or improperly sutured, than by the occurrence of the tear itself.

Respirations in the baby were spontaneous in forty-six cases, and required artificial aid in thirteen cases. Methods used ranged, after laryngeal aspiration, from spanking to hot and cold tubbing, artificial respirations, Schultze swinging, and direct tracheal insufflation by catheter. Four were oligopneic and six were asphyctic, requiring constant watching and in two cases repeated resuscitations.

The one stillbirth occurred in Case 62, rupture of the uterus, with escape of the fetus into the abdominal cavity and prompt death.

Of the "late lasting symptoms," the patients complained most of blurred vision; eight were pronounced, lasting over twenty-four hours; nine patients had cloudy memory lasting over six hours postpartum, and two had marked delirium, persisting two and four days postpartum. Who can read such statistics, knowing the care with which this work was done and the safeguards that were thrown around the cases, and not feel out of patience with those who seemingly are trafficking in the natural fears of pregnant women?

After-pains were noteworthy in eight cases, six in primiparas, a larger proportion than is usual; involution, breast engorgement and lactation were not influenced. Our mothers nurse their babies, the babies do well, and are taken off the breast only on the rare occasions when a threatened breast infection requires radical action to avoid pus formation.

"The exhaustion of labor" has always been conspicuous by its absence in the wards of the Michael Reese Maternity, excepting in the occasional pathologic primiparas, and even these are usually alert on the second day. We find it hard to understand this phrase, graphic though it is, for there is seldom a day when on making rounds it is not necessary to insist that some recently delivered woman get off her elbow, stop entertaining her neighbors, and lie down. The women are permitted to turn frequently, and after four days are encouraged to lie face downward the greater part of the time and so favor anteflexion in involution. All patients sit up in bed on the eighth day, get out of bed on the ninth and go home on the eleventh day (many on the tenth at their own request because they feel so well).

Spontaneous delivery of the placenta occurred only twice, fifty-seven cases requiring the Credé expression, which is not attempted until thirty minutes postpartum even if a placental pole shows at the outlet. In the untreated series of sixty cases there were five spontaneous expulsions. The single manual removal occurred in the case of ruptured uterus.

Blood pressures taken on admission and immediately postpartum showed an average drop of 5 mm.

There were seven postpartum hemorrhages, none of which required packing, but were variously controlled by holding the fundus (not massaging), vulvar compression, ergot and pituitary extract hypodermically, and temporary compression of the abdominal aorta. This compares unfavorably with the untreated series of sixty cases in which only one postpartum hemorrhage occurred, but is surely explained by the enfeebled contractions, the lengthened labor and the restlessness of the patients.

That frequent bimanual examinations are not necessary, even in such a series as this in which the patient is so unreliable a guide, is proved by the small total of seventy-seven in sixty cases, in spite of which no obstetric indications were overlooked.

From the foregoing results it seems reasonable to conclude that there are such dangers connected with the administration of the drugs, and that there is such a striking uncertainty of action in any given case, that the routine adoption of the treatment is not to be considered; moreover, it has been found impossible to "select" cases on any intelligent basis.

The lay press and magazines in their anxiety to outdo one another have published articles filled with the most extravagant phrases, but it is a bit out of the ordinary to read of a medical enthusiast announcing that by this treatment *the horrors of the delivery room are avoided*. The women must be few and far between who look back on the room in which they gave birth as a "chamber of horrors."

SUMMARY

The prolongation of labor, the increase in the number of fetal asphyxias, the excessive thirst and intense headaches that are so distressing, the difficult control of patients and avoidance of infection by soiling of the genitals, the more frequent postpartum hemorrhages, the blurred vision, the ghastly deliriums persisting far into the puerperium, the inability to recognize the onset of the second stage unless by risk of more frequent examinations, the masking of early symptoms such as antepartum hemorrhage, rupture of the uterus and even eclampsia, the violence and uncertainty of the whole treatment, the general bad impression given to our patients who are being taught to approach the "horrors of labor" in fear and trembling, constitute so severe an arraignment of this treatment of labor cases that we feel compelled to condemn it, leaving open the question of the merits of a single dose of morphin and scopolamin in those cases in which we have hitherto given morphin and atropin.

New Feature of Antifly Campaign.—At Buffalo in order to encourage and promote the antifly campaign the health department has inaugurated the plan of granting a certificate to the proprietors of all places of business who will make war on flies and certify on honor that there were no flies in their places on the first days of June, July, August and September. This it is believed will prove effective in increasing efforts against the fly nuisance. As suggestions in the way of fly extermination and prevention the following are offered: "Kill all winter flies, the egg-layers; clean up the premises and keep them free of dirt, refuse, manure, garbage, etc., the breeding places; screen all windows and doors; cover garbage cans and manure boxes; place fly traps in April; get the neighbors interested."

SCOPOLAMIN AND NARCOPHIN SEMINARCOSIS DURING LABOR[*]

WALTER E. LIBBY, M.D.
Assistant in Obstetrics and Gynecology, University of California Medical School
SAN FRANCISCO

The conservative attitude of American physicians toward the use of scopolamin and morphin during labor has been chiefly due to the lack of uniformity in the results obtained in the various German clinics, for in that country the method was devised and has been steadily improved. In a number of obstetric cases recorded by Schneiderlein,[1] anesthesia obtained by this means proved fatal in one instance, and subsequently the use of these drugs for the purpose of obtaining complete anesthesia has not been advocated. A smaller dosage, as Steinbuchel[2] found, would induce seminarcosis which was safe for the mother. While in this state the patient may be sensitive to pain but is unable to remember that she suffered, or in fact, to remember anything which occurred during the course of labor. This method of treatment, therefore, does not produce anesthesia, but seminarcosis and amnesia.

Steinbuchel's technic, however, did not yield satisfactory results in the hands of Gauss,[3] who was stimulated to seek better means for regulating the administration of the drugs. Later Straub sought a more stable preparation of scopolamin. Such precautions were necessary to prevent overdosage and to avoid decomposition products of scopolamin which are toxic. Gauss believed that administration of these decomposition products, especially apoatropin, accounted for the untoward symptoms which Hocheisen[4] frequently observed and which led him to denounce emphatically the use of scopolamin in any case. But, even after the required stable preparation had been procured and the technic standardized to give uniform results in Freiburg, the reports from other European clinics varied. In Berlin, for example, Strassman[5] observed when scopolamin and morphin were used that uterine contractions were frequently impaired, and even more frequently that the fetus was asphyxiated; and for these reasons Strassman did not recommend the treatment. On the other hand, the results in Döderlein's clinic in Munich reported by Zweifel[6] have been encouraging.

The fact that efforts are being made continually to simplify and perfect the method also indicates that it is still in the experimental stage. In May, 1914, Siegel,[7] one of Krönig's assistants, reported a series of 220 cases in which narcophin was used to replace morphin. The repeated administration of both drugs was based on a time-schedule, and not on various tests which Gauss has employed. Siegel came to the conclusion that narcophin had less effect than morphin on the child and that the lapse of a given interval of time could generally be relied on as an indication for the need of additional doses of one or both drugs. As this report represented the last word from the Freiburg clinic and the results were as good as, if not better than, those previously reported we selected for trial the procedure which Siegel recommended. My conclusions, therefore, are based on the observation of thirty-five cases in which scopolamin and narcophin were administered. All the patients had normal pelves and in every instance the fetus presented by the vertex. In other words, if normal obstetric conditions did not prevail, we have not ventured to employ the treatment; nor have we used it in the case of elderly primiparas.

---

In each instance the treatment was started when there was definite evidence that labor had begun, or when the patient was admitted to the hospital somewhat advanced in labor. The first dose has usually been given when the pains were from five to ten minutes apart, and at this time the cervical dilatation was found to be 2 cm. or more in the case of primiparas, 4 cm. or more in the case of multiparas. In the earlier cases of the series the sequence of doses was arranged according to Siegel's schedule, but later it was found more satisfactory to depart somewhat from that routine.

SIEGEL'S SCHEME OF DOSAGE

Dose		Amount	Interval
First	Scopolamin	.00045 gm. (1.5 c.c.)	
	Narcophin	.03 gm. (1 c.c.)	
Second	Scopolamin	.00045 gm. (1.5 c.c.)	45 minutes after first dose.
Third	Scopolamin	.00015 gm. (.5 c.c.)	
	Narcophin	.015 gm. (.5 c.c.)	45 minutes after second dose.
Fourth	Scopolamin	.00015 gm. (.5 c.c.)	1½ hours after third dose.
Fifth	Scopolamin	.00015 gm. (.5 c.c.)	1½ hours after fourth dose.
Sixth	Scopolamin	.00015 gm. (.5 c.c.)	
	Narcophin	.015 gm. (.5 c.c.)	1½ hours after fifth dose.

According to Siegel's scheme, subsequent doses are administered every hour and a half as illustrated in the latter part of the table, and narcophin is added to every third dose of scopolamin. Thus the third, sixth and ninth doses contain scopolamin 0.00015 gm. and narcophin 0.015 gm. The intervening doses consist simply of scopolamin.

If this schedule was implicitly followed, we found occasionally that uterine contractions ceased, or the infant was born deeply asphyxiated. Consequently, we have limited the use of narcophin to the initial dose unless the effect of that dose was insufficient or wore off. And I agree with Knipe[8] that it is not always possible to regulate the dosage of scopolamin on a time basis. Nevertheless, such an outline as Siegel has provided will be found very helpful when beginning the use of this treatment, and the schedule has been satisfactory for more than half our cases. Whenever the patient is deeply narcotized and the uterine contractions are becoming impaired, the next dose indicated in the schedule should be deferred or dropped altogether.

Our solutions were prepared in the hospital pharmacy from the scopolamin manufactured by Hoffman-La Roche and from the narcophin manufactured by Boehringer Söhne, since these were the preparations Siegel recommended. The solutions were made so that 1 c.c. of the one contained 0.0003 gm. scopolamin, and 1 c.c. of the other 0.03 gm. narcophin. At any one time only small quantities of the solution were prepared, for it is most important that fresh solutions be used. With age they deteriorate and become ineffective, or on the other hand decompose, giving rise to toxic substances. If a white flocculent precipitate appears in the scopolamin solution, it should be thrown away. Following the use of such a mixture, Gauss observed severe postpartum hemorrhage and deep asphyxia of the infant.

The drugs were administered with an ordinary hypodermic syringe. At the time when the required dose included both scopolamin and narcophin, the solutions were mixed in the syringe. The site of injection was the upper arm; first one and then the other was utilized. A subsequent local reaction was noticed in one case but this was negligible. The average number of doses of scopolamin administered was from five to six; the largest number was thirteen and the smallest two.

Except in five cases, chloroform inhalations were employed toward the conclusion of the second stage of labor. These exceptions were made in order to learn what conditions prevailed if scopolamin-narcophin narcosis alone was employed, as the head passed through the vulva. These patients were multiparas and, although they remembered nothing of the delivery, I believe that aseptic measures can be better carried out if chloroform is administered.

Our cases included eighteen primiparous and seventeen multiparous women. As has been frequently noted, patients differ in their susceptibility to the drugs in question, and such differences bear no relation to parity. Approximately 17 per cent. of our cases (six instances) not only experienced pain and remembered it, but also remembered other things which happened while they were in labor.

In a typical successful case the first effects appear about fifteen minutes after the initial dose. The patient experiences a "heavy feeling" in her head, and becomes drowsy; later she falls asleep to awaken with each painful uterine contraction. Generally, when an attendant enters the room the patient will pay no attention and, if questions are asked, she may seem unable to comprehend their meaning. Muscular twitchings were noted in twenty-three instances. Similarly, in about two-thirds of the cases thirst was a conspicuous symptom.

Not infrequently circulatory disturbances were observed, but these have never been of an alarming character; and it is difficult to decide to what extent these symptoms should be attributed to the treatment. Some of them are familiar during the normal course of labor as, for example, flushing of the face, which in this series appeared twenty-four times. Marked injection of the conjunctivae occurred four times.

Variations in the pulse rate were not uncommon during the early part of the narcosis. The most extreme effect of this sort was exhibited by a patient whose pulse varied between 64 and 140. Arrhythmia also was occasionally observed. A slight acceleration of the pulse occurred in half our cases, most frequently after the second or third injection. Subsequently, there was a tendency for the count to become normal; but in seven cases the pulse rate varied notably during the whole course of labor. On the other hand, respiration was not affected by the dosage we have used.

Generally, as the narcosis became more and more profound, the patient was inclined to sleep, or at least remained quiet and unconcerned. As a rule, when aroused and given instructions she obeyed (thirty cases), but in two instances while the directions seemed to be understood, the patient would make no effort to bear down. Occasionally toward the end of the second stage of labor, patients became excited, even violent, and almost unmanageable. This complication occurred in three instances (about 8.5 per cent.); according to other observers, its frequency is as follows: Gauss 1.4 per cent., Preller[9] 1.7 per cent., Hocheisen 10 per cent., Steffen[10] 13 per cent., and Mayer[11] 26 per cent.

---

[8] Knipe: The Freiburg Method of Dammerschlaf or Twilight Sleep, Am. Jour. Obst., 1914, lxx, No. 6, p. 884.

A prolongation of labor due to the use of scopolamin and an opiate has always been admitted, and may occur in a fourth of the cases (Hocheisen, Steffen, Avarffy[12]). Strong advocates of the treatment estimate the amount of prolongation as something less than we have found. From our observations it appears that labor may be prolonged three or four hours in the case of primiparas. In multiparous women there is an average delay of an hour. Thus, the average duration of the first and second stages in this series was twenty-one hours in the case of primiparas and twelve hours in the case of multiparas. The corresponding figures for normal cases are eighteen and eleven hours, respectively.

In the first stage of labor the contractions may or may not be impaired. Approximately four fifths of our patients were unaffected, but in the remaining cases the contractions became weaker and the interval between them longer. In two instances, contractions ceased completely after three doses; there was an interval of two hours in one instance and three in the other before they were reestablished. With both these patients the treatment was begun early in labor, and evidently it is exceedingly important that the "pains" become regular, and at least ten minutes apart before the initial dose is administered.

Unless frequent examinations are made, it becomes difficult to determine when the first stage ends. Generally, we have employed rectal examinations, and have based our estimates on those findings. However, it is noteworthy that as a rule, patients who have been quiet become restless when they enter on the second stage of labor. This observation has a practical significance, for, if seminarcosis is employed, the obstetrician must learn when the cervix is fully dilated in order to instruct the patient to bring voluntary effort into play. If not told to do so, while under the influence of scopolamin and narcophin, she will not assist the expulsion of the fetus. Generally the response to advice is prompt and satisfactory; otherwise pushing down on the fundus or grasping the hands and pulling on the arms of the patient at the proper moment usually arouses her to employ her abdominal muscles. Once the idea is grasped, there is no trouble in securing continued cooperation. The retardation of the second stage of labor chiefly depends on the difficulty of getting the patient to bear down.

Pituitary extract was given in nine cases and was effective in only three. But in no case was more than one dose administered. It is pertinent that in two instances in which the pituitary extract had no effect there was also no narcotic influence from the scopolamin and narcophin, although in one case eight doses had been given according to Siegel's schedule, and in the other case eleven doses. We have found that pituitary extract does not stimulate patients in seminarcosis to employ their abdominal muscles.

There was a frank indication for the use of forceps — usually after pituitary extract had failed — in six cases in this series, four primiparas and two multiparas. Twice the operation was a mid and four times a low forceps. In all these cases, although the patient had been in the second stage two hours, there was no advance. The failure to progress was explained more frequently by the patient's lack of inclination to assist herself than by inefficient uterine contraction. Two patients who required the use of forceps were unmanageable in the second stage, and after the lapse of two hours were delivered under chloroform anesthesia. In another case no effect had been secured from scopolamin and narcophin, and forceps were employed on account of a rigid perineum. Excluding the last instance, the frequency of forceps operation (14 per cent.) remains greater than we have previously been accustomed to. And our experience accords with that of Fehling, who considers that if scopolamin is used, the frequency of operations is approximately doubled.

The third stage of labor was uninfluenced by the administration of scopolamin and narcophin. In one instance an hour after the patient was delivered a moderate postpartum hemorrhage occurred, but this was due to temporary atony such as we encounter once in every forty or fifty multiparous patients, even though delivered without any anesthetic. Massage and pituitary extract were promptly effective, and the excessive bleeding did not recur.

Following labor the narcosis passed away in from two to four hours. The return to normal mental conditions, however, depends on a number of factors, as the amount of the drugs administered and the extent to which the patient is aroused by her attendants and surroundings. The puerperal convalescence is uninfluenced; as one makes rounds of the wards he cannot distinguish patients who have received scopolamin and narcophin during labor from those who have not.

Obviously, the effect of scopolamin and narcophin seminarcosis on the fetus is a matter of prime importance. During the labor the fetal heart sounds were observed as a routine every half hour, and in some cases more frequently. In no instance was there an appreciable effect on the character of the sounds, and also the effect on the rate has been negligible. The lowest fetal heart rate was 116, and the highest 176. Naturally, in individual cases there has been some variation between the counts made at different times, but again here we have not noted anything unphysiologic. The difference between the highest and the lowest counts averaged 17 beats to the minute.

While delivery was taking place, meconium was passed in four instances, but none of these infants was deeply asphyxiated, and two cried as soon as they were born.

The establishment of respiration in the new-born infant is frequently delayed when the mother receives scopolamin and narcophin during labor, and in these circumstances the delay depends on the narcotized state of the infant. Slight asphyxia (oligo-apnea) was present in six instances; but in these cases there was no cause for anxiety, for a few slaps on the back promptly made the infant cry. Deep asphyxia (apnea) also occurred in six cases (17 per cent.), and although all these infants were resuscitated, vigorous measures were required for a period of fifteen or twenty minutes. Most of the cases of apnea occurred early in our experience. It is also noteworthy that deep asphyxia appeared most frequently when the mother received only a few doses of the treatment. This fact, we believe, is explained by the relatively larger dosage of narcophin at the beginning than toward the end of Siegel's schedule. Acting on this conviction, whenever the first stage of labor was well advanced before the treatment was begun, we have made it a rule to give only the initial dose of narcophin. Moreover, in all cases the administration of the opiate should be guided by the requirements of the individual patient — not by a time schedule. Since we adopted these precautions, cases of asphyxia have become less frequent. But our experience teaches that narcophin is open to the same objection as morphin, and its use offers no advantage over that of morphin.

Another precaution of no slight importance consists in making the infant cry lustily as soon as it is born. If the physician is content that regular respirations have become established, and before the baby cries entrusts its supervision to a nurse, he may later be notified that the baby has collapsed. In a case of this kind, although only a few minutes had passed since the infant was handed to the nurse, we had considerable difficulty in reviving it, and half an hour elapsed before we were successful. In any case, if scopolamin and an opiate have been used, the infant should be carefully watched for at least an hour and sometimes longer, for the drugs are transmitted through the placenta, and a smaller or larger amount of them is present in the fetal circulation at the time of birth.

None of the infants in our series died as a result of the use of the drugs in question. However, there was one fetal death which occurred on the second day after birth. Clinically the diagnosis was malformation of the heart, and the necropsy revealed a perforate interventricular septum, stenosis of the pulmonary valves, and marked dilatation of the pulmonary artery. Evidently these lesions were congenital.

After the first day of life, the effect of scopolamin and narcophin on the infant may be disregarded. In their development, the infants whose mothers have received this treatment behave like others. There is the customary initial loss of weight, and this is not exaggerated. The birth weight is regained toward the tenth day, as in other cases. Furthermore, this method of narcosis exerts no baneful influence on lactation.

It is the difficulty occasionally encountered in resuscitating the infant which provides the chief objection to the use of scopolamin and an opiate during labor. And while we have met no case in which resuscitative measures failed, the prolonged efforts occasionally required enable us to understand that fetal deaths may result from the treatment. In Chrobak's clinic, one fetal death in 107 cases seemed chargeable to scopolamin and morphin, and Avarffy recorded one fetal death in fifty cases.

On the other hand, we are strongly encouraged by the testimony of mothers to continue the use of scopolamin and narcophin seminarcosis in obstetric cases. In those which we have observed, approximately four fifths (twenty-nine patients) remembered nothing which happened after they were under the influence of the drugs, and were unaware that the baby was born until they were told; therefore, these may be counted successful cases. Patients always have a clear recollection of the first dose, frequently of the second and sometimes of the third. As a rule, satisfactory narcosis is secured between the second and third doses, about two hours after the treatment is begun.

In two instances—so-called partial successes—there was a clear memory of everything which happened during labor, but these patients considered that the treatment had modified their suffering. In four instances the treatment had no effect whatever on the mother. Therefore, our experience teaches that once in six or seven cases (17 per cent.) scopolamin and narcophin will not have the effect for which they are administered. Siegel also admits 12 per cent. of failures. Similar results are observed if morphin is used in place of narcophin. Thus, Tischauer,[13] who collected 2,270 cases, found that the frequency of failures, in the reports of observers outside of Freiburg varied from 20 to 54 per cent.

No injurious effect on the mother was encountered in our experience, but it must not be forgotten that we have rejected cases in which complications of labor were anticipated. With this caution, and if the patient understands that some difficulty occasionally arises in reviving the child, her wish to receive scopolamin and morphin or narcophin seminarcosis during labor may be complied with. However, physicians must recognize that the method has not reached the perfection which warrants indiscriminate use. For example, even moderate degrees of pelvic contraction make it inadvisable to employ seminarcosis, for in these circumstances its effects may diminish the chances for spontaneous delivery and occasionally necessitate the performance even of major obstetric operations. Similarly, the primary inertia not infrequent in the case of elderly primiparas constitutes a contraindication to the use of scopolamin. For the present, therefore, it would seem advisable to employ this drug only when there is every indication that the patient will pass through a normal confinement.

An intimate knowledge of obstetrics is required if physicians wish to administer seminarcosis successfully, for sound judgment must be exercised not only in the selection of cases but also in the management of labor. The supervision of patients who are under the influence of scopolamin and an opiate requires competent assistants. For this reason, and also because the frequency of operative procedures is increased, good hospital facilities are desirable. However, such precautions do not mean that the method is impracticable and that it ought to be discarded. On the contrary, the very satisfactory results in the majority of cases provides the stimulus to secure further improvements in the method which will broaden its field of application and remove its objectionable effect upon the new-born infant.[14]

Prognosis.—I suppose prognosis is more difficult than diagnosis, because in the latter one still has Nature in consultation; when it comes to a question of prophecy, the doctor is pitting his opinion against that of the Senior Practitioner. —Adolphe Abrahams, *Practitioner*, March, 1915.

MECHANICS AND PATHOLOGY OF TUBERCULOUS HIP-DISEASE IN THEIR RELATION TO ITS DIAGNOSIS AND TREATMENT

P. W. NATHAN, M.D.
NEW YORK

Some years ago, when I began a study of the cases of hip-disease which were then, and had been treated at the Hospital for Ruptured and Crippled, I began, at the same time, to study the literature on this subject. I soon discovered that there existed a great diversity of opinion regarding the treatment of this condition.

It was admitted on all sides that we were dealing with a disease for which we had no specific remedy, and that our only resource was to treat the condition from a purely mechanical point of view. As usually stated, the idea was to maintain the affected limb at rest in order to allay the inflammatory reaction; it was to be held in a manner which would permit of locomotion, so that the patient might obtain the benefit of fresh air and exercise; and finally the brace or apparatus to be used for this purpose should be so constructed that the limb would be in the best possible position for locomotion when the disease was cured or arrested.

In a word, the treatment for tuberculous hip-disease was, and, for that matter, still remains, a question of mechanics.

Now mechanics, as is well known, is a mathematical science. Such being the case, there should not be a diversity of opinion as to the mechanical requirements or the methods of fulfilling them. Given similar conditions, the indications must be similar. Hence, with a diversity of opinion as to the methods, it must be assumed that some or all of the methods in use for the treatment of hip-disease are inadequate.

It was in order to discover, if possible, the exact mechanical requirements to be fulfilled in the treatment of hip-disease, that I then began the study of the anatomic mechanics of the normal, as well as the tuberculous hip-joint, in connection with my clinical studies. The results of these studies cannot be presented in their entirety at present. I feel, however, that the importance of the subject justifies the presentation of some of the conclusions, though there can be only a brief allusion to the details of the work on which they are founded.

I shall call attention only to the few anatomic and mechanical details which bear directly on the questions to be discussed.

Of all the organic joints, the bones of the human hip-joint most closely resemble ideal geometrical figures. The head of the femur is part of an almost perfect sphere; it is, during life, closely embraced by the acetabulum and the cotyloid ligament; and these together form an almost perfect ball and socket joint. Hence this joint is in every way comparable to the inorganic ball and socket joint of the technician, and as such, is subject to the same mechanical laws and advantages.

Unfortunately, with the advantages which this perfect mechanical form brings, there exists the disadvantage, that slight incongruities of the articulating surfaces lead to marked impairment of function. It is for this reason that conditions which in other joints, would cause only a slight impairment of function, that in time might be compensated for, lead to marked and often permanent damage in the hip-joint.

The extent of motion in the hip is considerably augmented by the length and slenderness of the neck. Here again the mechanical advantages of the structure are in a measure offset by the disadvantages which arise from this form; namely, great liability to distortion and consequent impairment of function under pathologic conditions.

In by far the majority of cases of tuberculous hip-disease, the lesion lies in the articulating bones. Roentgenoscopy in a large number of cases has borne out the pathologic investigations of the older writers in this respect. My own investigations have led me to believe that not only are the bones practically always affected, but that, in the majority of cases, the bone lesion is the primary one.

In a small percentage of cases the lesions may be in the neck outside of the capsule or in the trochanter, and, remaining so, the joint does not become involved. When this is the case the patient of course recovers with perfect joint function.

In by far the greater number of cases, the bones within the articulation are affected. In my own cases, the neck, the head, and the acetabulum were primarily affected in about the same proportions.

No matter where the disease begins it rarely remains focal. Not only does the actual focus extend, but surrounding it for some distance is an area of inflammatory atrophy, which, in the milder cases, may be moderate and more or less limited in extent. In the average case the inflammatory atrophy is marked and extensive; and in the severe ones, it leads to extensive bone absorption; separation or absorption of the head; complete absorption of both the head and neck, deepening or enlargement of the acetabulum alone, or in combination with the previously mentioned changes in the femur.

These changes depend on the character of the pathologic condition. I have seen them occur in cases treated by all known procedures. Braces, bed extensions, plaster spicas long and short, are powerless to prevent them.

Any one who will follow a large series of cases, treated according to any method will find this to be true. I have roentgenograms of a number of cases treated by means of the long-extension hip-brace (which is supposed to prevent absorption and destruction) which illustrates the usual course of events.

Hence, it is evident that not only have we no specific remedy, but we have not even the means to prevent or check the mechanical damage induced by the pathologic process.

This being true, what is the ultimate outcome of the condition? As we have no apparatus which will prevent atrophy and absorption, can we by the use of an apparatus retain the parts in their normal relations until some reparative process will restore, in a measure, the normal density, contour and relation of the affected parts? My experience leads me to believe, that restorative processes in hip-disease are practically absent.

If one follows the course of a number of cases of hip-disease, making frequent careful clinical and roentgenographic examinations it will be found that the course and final outcome will only vary within certain limits.

All the cases seen during the early stages will present nothing more than the symptoms of hip irritation;

that is, the same reaction which any inflammatory or irritative condition in or near the joint will induce. The hip-joint, depending on the degree of the irritation, will be held more or less firmly in a position of flexion, abduction and slight external rotation. It is held in this position not because there is a specific irritation of the muscles which maintain this position, but because this position produces the most complete relaxation of the hip under the existing mechanical conditions. Because of the course of the muscles which surround the hip-joint and the peculiar construction of the capsule and its accessory ligaments, this position must be assumed in order to produce relaxation. Whether the position assumed is voluntary or involuntary is beside the question.

At this stage it is impossible to make a positive diagnosis of tuberculous hip-disease, for the same symptoms will be present in all forms of inflammation in the joint or its neighborhood. In my own cases, I consider that I am not dealing with tuberculous disease when patients presenting these symptoms get well with perfect function, unless I can demonstrate an extra-articular focus by means of the roentgenogram.

Even when, as the subsequent course of the disease demonstrates, we are dealing with tuberculosis, roentgenoscopy shows definite changes in only a small percentage of cases at this time. I have rarely been able to demonstrate an actual focus during the early stages.

After a variable length of time, a symptom-complex occurs, which the older writers describe as the second stage of the disease. It has been the practice of late years to ridicule this division of the disease into two stages; yet, though the transition is gradual and the two stages of the disease cannot always be definitely separated clinically, what has been called the second stage of hip-disease undoubtedly corresponds more or less closely to certain definite pathologic and mechanical conditions.

It is at this stage that the bone atrophy and bone absorption with the consequent deformation begin. The course from now onward can be traced by roentgenoscopy. We are by this means enabled to say definitely whether or not we have femoral or acetabular disease or both.

Clinically, both these conditions manifest themselves in the same way so far as the deformity is concerned. That is, in both these conditions the result is adduction deformity.[1]

The adduction like the abduction deformity is due, not to the specific nature of the disease, but to mechanical conditions. As has been said, the abduction is assumed to relax the hip-joint. That this position cannot be retained by muscular action alone, irrespective of other conditions, must be self-evident to every one with a knowledge of muscle physiology and mechanics. Whether the muscular contraction which holds the hip in the abducted position is caused by so-called muscular spasm or is voluntary, the power of the muscles engaged in producing this position is entirely inadequate to retain it for any great length of time. The force of gravity soon overcomes it, and when there is no deformation (for instance, in synovial conditions which, by the way, are much more uncommon in the hip than in the knee) the limb will fall and will finally become adducted, unless prevented from doing so by some external force.

When there is no deformation of the bones the cause of the adduction deformity lies in the efforts of the patient to save the leg from weight-bearing. Unable to retain the abducted position to relax the hip, the patient tilts the pelvis on the other hip so that the foot of the affected limb barely touches the ground. This position becomes permanent, that is, we have what is known as adductor contracture; not because the adductor muscles contract actively, but because the distance between the origin and insertion of the adductors is lessened, and according to physiologic laws these muscles accommodate themselves to this distance. When there is deformation of either the femoral or acetabular part of the articulation, the normal angle between the neck and shaft of the femur or the normal angle between the mechanical long axis of the limb and that of the shaft of the femur is so changed that mechanically the limb must become adducted.

The position of adduction will occur either during or after treatment in practically all cases of hip-disease, unless the limb becomes firmly ankylosed in the abducted position. If the patient has been on a brace, the brace sometimes, certainly not always, will hold the limb in a straight line for the time being. As soon as the patient begins to walk, however, he acquires an adduction deformity. Cutting the adductors, stretching and even osteotomy of the femur will not prevent its recurrence.

It is needless to discuss the disadvantages of this position. Yet disabling as this deformity is known to be, it does not approach the disability caused by acetabular disease. In this case the femoral head is gradually pushed upward as soon as there is weight-bearing, until it becomes subluxated or completely dislocated. Such patients not only have an adduction deformity but must bear the weight of the limb on the more or less completely destroyed capsule and the gluteal muscles. The result is that these patients not only walk badly, but are exceedingly subject to hip-strain.

In all cases of recovery from hip-disease with distortion and motion, the final functional result, that is, the result in adult life (which is the only result to be considered), is poor in every respect.

Thus from a careful consideration of the anatomy, the physiology and the mechanics, I have been led to exactly the same conclusion as that arrived at by Lorenz empirically. That is, to judge from the pathologic and mechanical conditions, I believe that the only result which can give the patient a really useful limb in adult life is one with bony ankylosis.

Whether or not we can attain this result by means of the short spica is another question. There can be no doubt that the ultimate mechanical requirements are much more likely to be fulfilled when the limb is held in the most advantageous position with regard to weight-bearing, than with any of the methods of treatment at our disposal at present. The tuberculous process in the bones is attended by a minimum of inflammatory reaction. It is only by weight-bearing or motion that we can stimulate the reaction processes to bone formation and thus increase the prospects for bony ankylosis.

---

[1] The location of the disease, when it is not so acute that the patient resists all attempts to move the joint, can in a measure be ascertained by physical signs. From the examination of many cases, comparing the joint symptoms with the roentgenogram and what the mechanics of the condition would lead one to expect, I have learned to locate the site of the disease even without roentgenoscopy. For example, a high trochanter with limitation in abduction, the other movements being free, is indicative of acetabular disease. When all motions are limited except flexion and extension (rare in tuberculous hip-disease but not so uncommon in senile osteo-arthritis of the hip), there is central acetabulum disease leading to intrapelvic displacement of the head of the femur; when the neck alone is involved the objective signs closely resemble those of coxa vara, though in tuberculous hip-disease there is more general limitation of motion. A high trochanter with limitation of motion in all directions is indicative of marked deformation of the head of the femur. It must be remembered, however, that these differential signs can only be made out after the acute irritative symptoms (because the joint has been immobilized or the disease is arrested) have subsided.

Even when the treatment with the spica and weight-bearing is conscientiously carried out, unfortunately we do not always succeed in securing an ankylosis. I firmly believe that we should seek to produce ankylosis in all cases in which there is deformation or much atrophy, by operative measures as soon as the disease has become quiescent.

As all who have attempted to operate on these patients know, the conditions for operation are unfavorable in adult life. The exposure is difficult, the tissues are resistant and the adult does not withstand the operative measures nearly so well as do children. In children, on the contrary, the exposure is easy, the tissues are elastic and the operative risk is practically nil. Moreover, I think it a mistake to attempt to save atrophied bone. Healthy bone-surfaces should be brought into apposition, and weight-bearing, with the proper precautions, should be encouraged as soon as possible after the operation. It is of course ridiculous to expect stumps of atrophied bone to bear the weight of the body; they should be removed and if necessary the trochanter should be brought into contact with the denuded acetabulum.

Concerning the plaster spica treatment, the hip should be retained as nearly as possible in the middle position, that is, slightly flexed, abducted and only slightly rotated out. Eversion is a disabling deformity and should be scrupulously avoided. The spica, except when it is applied for the relief of irritative symptoms, need not, nor will it when it extends only to the knee, completely immobilize the hip.

It is, of course, impossible to give details; when a patient should be in bed, and when he should be up, will depend on the circumstances. Above all it should be remembered that there can be no invariable rules; for in every case the mechanical and pathologic conditions must be met as they appear in that particular instance. So, for instance, in the isolated acetabular cases, with enlargement of the acetabulum, it is often difficult to attain bony ankylosis, and sometimes impossible to prevent subluxation or dislocation even when the spica is worn constantly. In such a case I have used a Thomas knee-brace, so modified that there is a sole plate instead of extension rods and a snap joint at the knee, when the condition has become quiescent. In a number of cases so treated, I have been successful in preventing luxation for some years, even after the brace was removed. As none of these individuals have as yet attained their full height and weight, however, I do not know whether or not the result is permanent.

The conclusions here presented are based on a study of about two hundred cases. Particular attention was given to final results. By final results I do not mean that the condition at the time the patient was discharged with the disease supposedly arrested or cured, but the condition after such an individual had used his affected hip during adult life. I place absolutely no reliance on statistics, particularly those obtained by letter from patients or their family physicians who live at a distance.

The results of the study here presented in a somewhat general way may be summarized as follows:

Tuberculosis of the hip is a destructive disease, which practically always leads to marked impairment of the joint structures. So far as we know, there is no treatment which will prevent or limit the destructive process and we have not, therefore, a method which will prevent permanent impairment of joint function.

Such being the case, it must be admitted that we have no adequate treatment for hip-disease. For the present, we must be content to choose the method which will give the patient the strongest limb to stand and walk on, irrespective of joint motion or shortening.

At present the treatment with the short plaster-of-Paris spica, with all its shortcomings, is better than any other heretofore in use, provided it is scientifically carried out.

110 East Seventy-Eighth Street.

BENZOL IN LEUKEMIA

F. H. SMITH, M.D.
ABINGDON, VA.

Last year I described two cases of leukemia treated with benzol (benzene, C_6H_6) after the plan of Koranyi. This article[1] is so recent that it will not be reviewed here. The extensive bibliography on the subject is also omitted; it was reviewed then, and Sappington and Pearson[2] have given a list of the articles on the subject to the date of their own.

Suffice it to say now that the patient with lymphatic leukemia referred to has since died. As suggested, benzol was discontinued shortly after the paper was printed because it seemed to have no effect on the leukemic process. So far as we could see, benzol neither helped nor harmed the patient.

The second case, one of the splenomyelogenous type, has been under observation almost continuously since Aug. 23, 1913, nineteen months. The length of treatment exceeds any that I have seen recorded, itself a matter of interest. The case is interesting, furthermore, because of the confirmation of some of my impressions expressed a year ago: until now certain fixed opinions relative to the worth of the drug and its dangers have been arrived at.

The mass of data accumulating in so many months may be omitted; that part of them which seems to have a bearing is given in the accompanying table.

The several features of this table stand out almost without the need of comment. What I shall have to say is more in the way of the conclusions to which they seem to lead.

A year ago I expressed the opinion that "benzol is a remedy of remarkable potency in myeloid leukemia." In spite of all that follows which may seem to argue to the contrary, I am convinced that it is the most helpful of all known agents in the treatment of leukemia of this type. When it is recalled that the patient under consideration was a boy of 13 years when the treatment was started; that his spleen then occupied about four fifths of the abdominal cavity, and that the leukocytes numbered 499,000, one is justified in expressing surprise that he is still living.

---

[1] Smith, F. H.: Benzol Treatment in Two Cases of Leukemia, The Journal A. M. A., March 21, 1914, p. 921.

[2] Sappington, S. W., and Pearson, W. A.: The Leukemias under Benzol, The Journal A. M. A., July 11, 1914, p. 143.

Such a case in an adolescent would have been generally conceded to be hopeless prior to the benzol treatment. "There is no known remedy that seems even to stay the course of the disease. Once the diagnosis is positive, the case is hopless."[3] Yet this boy is still living, is attending to his school duties, expresses himself as being entirely well, and on casual observation would seem so.

That the result is due to benzol cannot be reasonably questioned. There has been no other treatment than that indicated in the table. Even a casual inspection of the table will force the conclusion that the drop in the leukocytic count is directly dependent on the exhibition of the chemical in sufficient dosage.

The effectual range of dosage has also been fixed for this individual case. One notes that only once has a dose of 25 drops three times daily been exceeded; that results have followed a dose of from 20 to 25 drops three times daily (4 to 5 gm. approximately a day). Any less dose seems worse than useless, as this case in one of its phases suggests that the leukopoietic system becomes immune in time to a dose which was leukotoxic perhaps but a short time before. If such a conclusion be true, then the smaller than effective dose may in course of time become actually stimulating to leukocytic generation. Larger doses have so far not been necessary, and as with all potent drugs, one's desire should be to keep the dose within the limits of potency on the one hand, and of safety on the other.

A second statement of a year ago is also amply confirmed: "Beyond a doubt, 'benzol is a two-edged sword.'" There is nothing more certain in benzol therapy than this: the practitioner who prescribes the drug without making frequent blood counts is courting disaster. We have only to point to the blood picture of the table to justify the statement that there is no possible way of guessing what the count will be on the basis of the last; and, therefore, of judging whether the dose should be held stationary, increased, decreased or stopped altogether. I am firmly convinced that such judgment must be constantly exercised, under the threat of having the disease jump out of bounds on the one hand, or of producing disaster on the other.

One can guess that the rise of the count after a fall will be slower and more gradual than a drop. This is illustrated several times in the table. Nothing in it is more striking than the abrupt way in which the count drops from a point around 30,000 to 6,000 or

COURSE IN A CASE OF SPLENOMYELOGENOUS LEUKEMIA

3. Cheney, W. F.: Leukemia in Childhood, Am. Jour. Med. Sc., 1912, cxliii, 22.

7,000. If the blood curve were ruled graphically, the chart would resemble a fever chart of a disease full of crises: it *is* a series of blood crises. In other words, the leukocytes have all along *stepped up* and *fallen down*. Just how gradual will be the step upwards cannot be calculated: one time in two weeks, another, in eight weeks, perhaps. The drop comes abruptly, but what is more important, "when we least expect it," if such an expression can be allowed.

Nowhere can the last sentence be better illustrated, nor can the potential dangers of the drug be better emphasized, than in the happenings recorded as of between June 1 and July 20, 1914. The patient had been getting the largest doses of benzol he had ever had, and at the end of a course extending over four months, it seemed to be making no impression on the leukocytic curve. So it was stopped, for the double reason that the treatment seemed at last ineffectual, and because I was afraid to continue such large doses. My surprise and interest was keen, then, to note a drop from 24,000 to below 7,000. The cells remained at or near this point on no benzol at all for six weeks. There seems but one explanation available, and that just now suggested: After an indefinite time and after an uncertain degree of saturation has been reached, the leukopoietic tissues seem not only to become immune to benzol, but are actually stimulated by it.

The effect of this experience is to cause doubt as to how to handle the drug when the count stays high when we are pushing it. Shall we stop, or shall we continue? I feel that if the patient has already been taking benzol for several weeks and the curve is still ascending, or even at a standstill, the safest plan is to stop it for awhile. The drop may come then. At any rate, one cannot get away from the reported cases in which, under benzol, the leukemia assumed a fulminant form, and the patient rapidly succumbed. Whether or not these flare-ups are due to the benzol is not clear; but there is a type of benzol poisoning which is certain: a practical loss of leukocytes with aplastic anemia superadded.

The leukocytes in stained smear are interesting. The appearance of the white cells indicates degeneration. It is hard to make a satisfactory count; transition forms, difficult to classify, are frequent. This, I believe, is a direct result of the benzol therapy. At least, I have never noted just this difficulty before. At any rate, myelocytes have been present in every smear examined. The red-blood-making tissue has never suffered objectively, unless it be in the last crisis, when for the first time a rare normoblast was found. Yet one must always sense the lurking danger.

Myers and Jenkins'[4] observation of the fluctuation of the size of the spleen, without any regular relation to the fluctuations in the blood count, has ample confirmation in my case. One cannot argue that because the count is normal, the spleen is not palpable, or the reverse.

From my experience I believe that benzol poisoning will be first indicated in the blood in some one of its phases. Though I have been constantly on the watch for other toxic manifestations, I have seen none. It is curious to relate that this boy has seemed for one and one-half years to be normal subjectively. He has never complained, except of frequent "head" and bronchial "colds." These have been as frequent when off as when on benzol. Otherwise his general condition does not seem to vary, whether his leukocyte count is high or low, whether he is taking benzol or not. We still have no proof that benzol is specific. Of one thing I feel certain: it has not, and it will not "cure" in this case. One may doubt whether such dogmatism is ever proper. Suppose the dose were raised? I believe that benzol poisoning would follow, nor is there reason to believe the case would be any nearer a cure for the risk. There is not the constant decrease of the size of the spleen, nor the constant falling off, to disappearance, of the myelocytes that would be expected were the drug's specificity dependent on a higher dose than any I have ventured.

In doubting its specific properties I admit a great disappointment. I had hoped that one more of the number of incurable diseases was soon to give way before specific therapy. Instead of this hope, I am confidently looking forward to the time when in spite of, if not because of, benzol, this patient's leukemia will assume one of three forms: a chronic progression upward of the leukocyte curve, a constant enlargement of the spleen, and ultimate death, just as if there had been no staying treatment, or an acute fulminant picture, in which the increase of the leukocytes will be by leaps and bounds to a high figure; or, on the other hand, a drop in the leukocyte curve will come, will not stop at the normal line, but will continue downward to 500 or thereabouts, with all the other evidences of aplastic anemia.

When all is said, however, concerning the disappointment in train of this experience, and of the dangers that lurk in its unguarded and largely empiric use, the chemical has a most remarkable *inhibiting influence* on the course of the disease. There is no exact analogy that I can think of. Like digitalis, however, benzol may have a distinct place in therapy, even if its action prove short of specific, and merely symptomatic, staying or inhibitory.

The Scope of Embryology.—The development of the egg has always cast a peculiar spell on the scientific imagination. As we follow it hour by hour in the living object we witness a spectacular exhibition that seems to bring us very close to the secrets of animal life. It awakens an irrepressible desire to look below the surface of the phenomena, to penetrate the mystery of development. The singular fact nevertheless is that during the phylogenetic period of embryological research this great problem, though always before our eyes, seemed almost to be forgotten in our preoccupation with purely historical questions—such as the origin of vertebrates or of annelids, the homologies of germ-layers, gill-slits or nephridia, and a hundred others of the same type. Now, these questions are and always will remain of great interest; but embryology, as at last we came to see, is but indirectly connected with historical problems of this type. The embryologist seeks first of all to attain to some understanding of development. It was therefore a notable event when, in the later eighties, a small group of embryologists headed by Wilhelm Roux turned away from the historical aspects of embryology and addressed themselves to experiments designed solely to throw light upon the mechanism of development. The full significance of this step first came home to us in the early nineties with Driesch's memorable discovery that by a simple mechanical operation we can at will cause one egg to produce two, or even more than two, perfect embryos. I will not pause to inquire why this result should have seemed so revolutionary. It was as if the scales had fallen from our eyes. With almost a feeling of shock we took the measure of our ignorance and saw the whole problem of development opened.—Edmund B. Wilson, *Science.*

GASTRO-INTESTINAL STUDIES

V. THE PROTEIN CURVE OF GASTRIC DIGESTION IN NORMAL AND PATHOLOGIC CASES *

J. ALEXANDER CLARKE, Jr., A.B.
AND
MARTIN E. REHFUSS, M.D.
PHILADELPHIA

TECHNIC OF THE REACTION AND FALLACIES OF THE TEST

Within recent years considerable interest has been shown in the study of the protein content of the gastric juice owing to the application of methods for the determination of this content in arriving at a differential diagnosis of carcinoma of the stomach and benign achylias. But little interest was manifested in the importance of the protein content in other conditions in which the acidity was present or pronounced. Furthermore, all methods which were evolved toward a solution of this problem considered the protein content merely from the point of view of a single phase in the gastric cycle. By means of a method recently devised by one of us, it has been possible to study the protein content systematically in every phase of digestion and to obtain data of importance. We have made a study of the principles underlying the reaction and shall endeavor to point out the fallacies connected with the ordinary method of examination. The regular Wolff technic[1] was used with slight modifications, but instead of testing the protein content at the one-hour interval, we tested specimens[2] throughout the entire period of digestion.

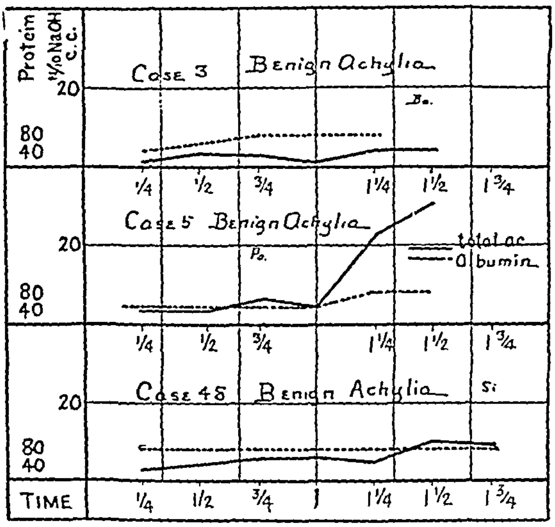

Chart 1.—Total acidity and albumin curves in three cases of benign achylia.

Readings were immediately made and the tube giving a ring at the greatest dilution of gastric juice was recorded.[3] In every instance it was desirable to perform the test under conditions which were as constant as possible, and for that reason readings were always made against a dark background. If the tubes were left standing for fifteen minutes or longer it was remarked that solutions of even greater dilution than the one recorded were capable of giving a ring. The importance of immediate examination is therefore insisted on. A second point should be brought out. The stomach should be empty. One of us[4] pointed out elsewhere that even normally a large residue is often found which may in certain pathologic cases assume exaggerated proportions.

In certain experiments (which one of us performed with Drs. Bergeim and Hawk) made in this laboratory, it was remarked that even relatively simple articles of diet such as eggs, combined with cereals and milk, may remain for relatively long periods in the healthy stomach. To commence a test five hours after such a diet will show, even in a certain number of normal individuals, an initial high protein content owing to the dissolved proteins still remaining in the stomach.

Case 23, for instance, demonstrates the results obtained when the test was performed too soon after the individual had ingested a meal of fish and vegetables. In this case the test was purposely performed at that time and the resulting figures show the unmistakable presence of protein residue. *If, therefore, high figures are obtained when the stomach should be empty, in the absence of other factors which we shall point out, an initial very high point is indicative of protein retention.*

Another point is worthy of consideration. The patient is warned to be particularly careful about swallowing oral and bronchial secretions.

An estimation of the protein content of saliva in six normal individuals showed that it gave a reaction in five cases at 1:80 and in one case for some unknown reason at 1:160. These figures can be greatly surpassed in the sputum encountered in certain pulmonary cases, and it is an everyday observation that these individuals swallow much of their sputum.

NATURE OF THE PROTEIN REVEALED BY THIS METHOD

The protein on various occasions found in the gastric juice must come from a variety of sources. Briefly enumerated it may come from food ingested, saliva or bronchial secretions swallowed, bleeding owing to an ulcerative lesion, regurgitation of intestinal contents, and finally *in cases in which there is a gastric lesion, from specific protein products derived from the lesion itself.*

That the pure gastric juice derived from normal individuals contains but little protein must be evident from the fact that on various occasions the juice obtained from normal individuals after the administration of a water meal (a test meal consisting of 200 c.c. of water which is aspirated at intervals) never showed a protein content exceeding 1:40. This is significant inasmuch as it indicates that the pure normal juice has a very low protein content, any increase of which must be of pathologic importance. But the customary Wolff test is performed by administering the ordinary Ewald test-meal and testing at the one-hour interval. Concerning this method we have some data from Wolff,[5] Einstein,[6] and Rolph[7]; the results, however, of testing merely one phase of the digestive curve is obviously wrong. It merely registers a single point in the whole mechanism of gastric digestion and gives no information regarding the elaboration of the protein, a point not without importance.

---

* From the Laboratory of Physiological Chemistry of the Jefferson Medical College.

[1] Wolff: Magen und Darmkrankheiten, Berlin, 1912, p. 217.

[2] These specimens were obtained by means of the fractional tube which one of us (Rehfuss: Am. Jour. Med. Sc., June, 1914, p. 848; New York Med. Jour., Aug. 22, 1914. Rehfuss, Bergeim and Hawk, The Journal A. M. A., Sept. 12, 1914, p. 909) devised. Specimens were obtained in this way at fifteen-minute intervals, and at five-minute intervals during the first fifteen minutes. One c.c. of the filtered juice was then diluted with 9 c.c. of water representing a dilution of 1:10; 5 c.c. of this mixture was again added to 5 c.c. of distilled water and a dilution of 1:20 obtained; this was again repeated, using 5 c.c. of the mixture last obtained and 5 c.c. of distilled water, and the dilutions were kept up until a series was obtained representing 1:10, 1:20, 1:40; 1:80, 1:160, 1:320, and if necessary 1:640 or more. They were then stratified with approximately 1 c.c. of the Wolff phosphotungstic acid reagent, care being taken that the liquids did not mix.

[3] This reagent consists of phosphotungstic acid, 0.3 c.c.; conc. hydrochloric acid, 1.0 c.c.; alcohol, 95 per cent., 20.0 c.c.; distilled water q. s., 100.0 c.c.

[4] Rehfuss, Martin E., Bergeim, Olaf, and Hawk, Philip B.: The Question of the Residuum Found in the Empty Stomach, The Journal A. M. A., July 4, 1914, p. 11.

We therefore made studies (1) to determine if possible the actual content of the test meal and its fluctuation during digestion, and (2) the modification of this curve in normal and pathologic cases. These latter are recorded merely in the hope that a possible interpretation may be obtained for some of the curious phenomena recorded.

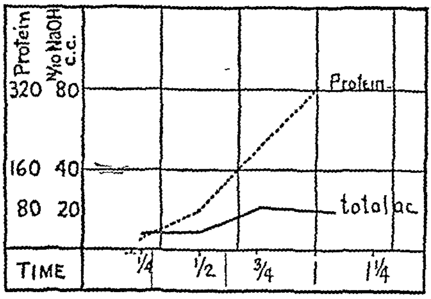

Chart 2.—Protein and total acidity curves in a case of gastric carcinoma.

We found that tea alone gave no reaction even at a dilution of 1:10, and that a regular Ewald meal consisting of 8 ounces of tea and two pieces of toast gave a reaction at 1:20, immediately after thorough maceration. After standing for fifteen hours in the incubator at 38 C. (100.4 F.) a reaction of 1:40 was obtained showing that there was practically no autodigestion. A solution of pepsin without hydrochloric acid gave no protein reaction whatever.

We then performed experiments to study the action of the artificial gastric juice in vitro. The macerated Ewald meal was treated by an artificial gastric juice made by dissolving 0.5 gm. of pepsin in 0.2 per cent. hydrochloric acid. The artificial juice failed to give a reaction at 1:10. This mixture was then put in the incubator at 38 C. and samples were taken at the same time intervals as were employed in taking specimens from the stomach with the fractional tube. The following results were typical of those obtained on three separate occasions:

5 minutes	1:40
10 minutes	1:80
15 minutes	1:80
30 minutes	1:160
45 minutes	1:160
60 minutes	1:160
75 minutes	1:320
90 minutes	1:320
105 minutes	1:320
120 minutes	1:320
18 hours	1:1,080

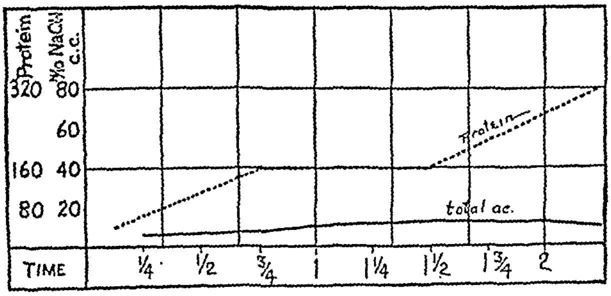

Chart 3.—Protein and total acidity curves in a case of gastric carcinoma.

Therefore we see that using this method we obtain a protein in gradually increasing quantities more or less directly proportional to the strength of the acid and the duration of the reaction and directly dependent on the soluble intermediate protein bodies formed through the action of the artificial gastric juice on the proteins of the bread. In each case there was a gradual rise as the continued action of the gastric juice made itself felt on the bread proteins. *If, therefore, the gastric mucous membrane is absolutely normal and there are no extrinsic sources of albumin, the protein curve should follow the acid curve and in the absence of acid should remain very low.* In other words, depending on the elaboration of acid, there should be a definite elaboration of soluble protein.

DIAGNOSIS OF CANCER FROM BENIGN ACHYLIA BY THIS METHOD

In an ordinary benign achylia, as seen in Case 5 and in Cases 24, 48 and 49, the albumin curve runs more or less parallel to the acid curve. Even in the subacidities due to benign causes the same rule holds true, and the albumin content remains comparatively low. Smithies,[8] Wolff[5] and others found that figures of 1:100 were suspicious and above this, point out positive evidence of neoplasm, but the actual evolution of the albumin curve was not worked out. We found that *in carcinoma the protein curve diverges from the acid curve, and as digestion progresses this disproportion increases so that there is a marked separation of the curves.* This is seen in the cases recorded (Cases 22, 26, 30 and 27) in which there was practically an achylia and in which in every instance, subsequent events and roentgenoscopy confirmed the diagnosis that the protein curve was entirely disproportionate to the acid curve. Secondly, that this increase in albumin concentration occurred as digestion proceeded suggested that there was an elaboration of protein on the part of the neoplasm per se. In other cases in which the neoplasm was accompanied by a demonstrable acidity, the protein was generally high with a tendency to become higher as digestion proceeded. Protein retention will result in high initial figures, but if the precaution is taken to empty the stomach before testing, this factor is disposed of. In the question of the differential diagnosis between cancer and benign achylia we wish to report two cases of considerable interest, which show how important it is to interpret the findings correctly.

Case 12.—A man, aged 44, suffering from gastric disturbances for many years, showed in the last few months before admission rather marked anorexia, profound anemia, a tendency to daily vomiting of yellowish material and mucus. He has lost distinctly in weight, and his anemia left him very weak, with paresthesias of the hands and feet. With the exception of intervals of mucus colitis, he has had rather marked constipation. The expectoration, which is pronounced, is free from tubercle bacilli, but contains many staphylococci, *Micrococcus catarrhalis* and a streptococcus. Physical examination as well as roentgenography fail to reveal anything in the lungs except a little thickening of the hilus of the right lung. From the character of the sputum, its persistence and the physical findings, we still thought (with Dr. Beardsley and Dr. Tracey of Beverley, to whom we were indebted for the case) that there must be bronchiectasis. Examination of the blood showed profound

anemia, but none of the true findings of pernicious anemia. An analysis of the gastric juice showed a total achylia persisting throughout the entire digestive cycle and absolutely no ferment response, occult blood positive, many smaller micro-organisms, but no lactic acid and no Oppler-Boas bacilli. The protein result is shown in No. 12 in the table. The sudden jump was synchronous with the appearance of bleeding and therefore was not due to the elaboration of the protein through a specific neoplasm, but to the protein in the blood exuded. Two things decided us against the diagnosis of neoplasm—first, the long duration of the case; secondly, the absence of any Roentgen-ray or palpatory evidence in the face of such a pronounced gastric finding. The case, which will be reported, is of the greatest interest. Suffice it to say, that by means of intragastric, dietetic and certain internal glandular medication, there was steady improvement with a disappearance of the gastric symptoms. A vaccine was made for the expectoration, and at this writing, after the fifth administration of the vaccine, the expectoration has disappeared, and the patient is 3 pounds over his best weight.

This case demonstrates forcibly the danger of taking the protein content at a given point and deciding for or against carcinoma of the stomach. Case 35 is similar, a direct infection of the stomach in a subject with purpura hemorrhagica, in which the presence of blood has caused a marked increase in the protein content. But in carcinoma, *the protein continues to increase until the end of digestion.* Case 22 is one in which there was a large inoperable carcinoma in the wall of the stomach. Case 27 is a similar case showing a gradual, steady and exaggerated rise in protein content. Case 30 shows to what extent this might go in carcinoma of the pylorus. In this case the retention liquid in the empty stomach was filled with a purée of leukocytes amounting to diluted pus; this was undoubtedly due to the ulceration of the neoplasm.

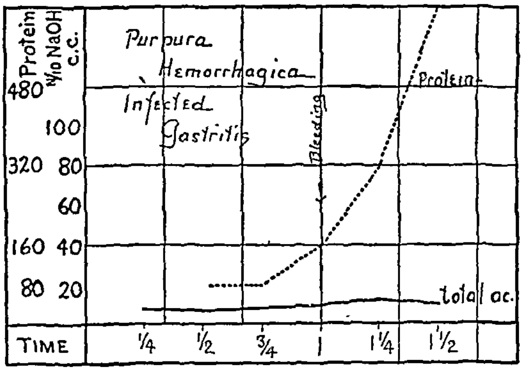

Chart 4.—Protein and total acidity curves in a case of purpura hemorrhagica.

DIAGNOSTIC VALUE OF THE PROTEIN CONTENT IN ULCERATIVE CONDITIONS OF THE STOMACH

We made a series of protein determinations on cases of clinically diagnosable ulcer, all of which had been submitted to careful physical examination and in most cases, roentgenoscopy. We found an altogether unusual protein curve in these cases, namely, a rapid rise in the protein concentration out of all proportion to the protein elaborated by the action of any juice in this period of time, arguing, therefore, for an extrinsic cause for the protein. This is to be seen in practically all cases on this list in which the diagnosis of ulcer was made, and the type of the protein curve in contrast to the acid curve is striking. Case 6 shows the very early initial rise. This was an undoubted case of gastric ulcer, showing the characteristic tender point, pain, and occult blood in both gastric contents and feces, and marked secondary anemia. The presence of the occult blood may be the cause for the phenomenon. In Case 8, which several clinicians thought one of gastric ulcer, the absence of characteristic symptoms, the absence of the minutest traces of bleeding, and the character of the curve enabled us to rule out ulcer. This was justified by the subsequent course of the case. Case 11, although the data are not complete, is in all probability one of ulcer, there being occult blood at times in the movements on a meat-free diet. Case 14 shows the recurrent pain, characteristic tender point, slight tendency to rigidity of the upper right rectus, persistent history of ulcer, and alimentary hypersecretion. Case 15 shows the persistently high protein content from a case of bleeding ulcer. The history is of long duration, characteristic pain, hematemesis, tender point, occult blood in the gastric contents and stools, and the early symptoms of gastric retention. Hypersecretion followed the meal and was pronounced. This liquid, which was found free from food residues, showed a protein content of 1:160, entirely different from the normal gastric juice. This was salted out with ammonium sulphate and filtered, and the albumin content dropped to 1:40, suggesting very strongly serum albumin probably derived from blood, as the cause of the high content. Case 16 was a typical case of ulcer with two severe attacks of hematemesis very large in amount, characteristic pain, both alimentary and continued hypersecretion, a tender point, and profound anemia from hemorrhage. Case 18 is one of pyloric ulcer with obstruction and retention, showing the very high point from the very first sample, undoubtedly due to protein retention. Cases 9 and 19 were cases of duodenal ulcer. Case 20 alone was puzzling, characteristic ulcer symptoms alternating with periods of relief. The case was most likely ulcer, high acid figures and hypersecretion playing an important part, although the evidence here renders the diagnosis uncertain. These cases are merely presented as showing a striking protein curve in cases of ulcer. Whether this is a constant finding, we are not prepared to state. We merely wish to submit these results for further investigation, believing that the high protein curve which does not occur in ordinary cases suggests the possibility of ulcer. As to the cause of this rise, whether it is due to bleeding, or hypothetically to exudation of protein products from the ulcer region, or to the action of the corrosive juice on the ulcer, we cannot say. Some further results seem to show that while the high protein content remains sustained in gastric ulcer, in duodenal ulcer there is an initial rise which apparently falls off more rapidly, possibly owing to the hypermotility encountered in a certain proportion of the cases of the latter disease. As yet we have insufficient data to make a definite statement, but in those cases in which the diagnosis was made the rise of the curve to its high point was slower.

METHOD OF INTERPRETATION OF THE RESULTS OF THE REACTION

In interpreting any protein curve, the question arises as to the quantity and source of the protein. We have pointed out that, normally, in the absence of any extrinsic factor, the quantity of dissolved protein runs more or less parallel to the duration of time in the stomach and the acidity. Any marked deviation must therefore be accounted for. On the basis of this finding rests the value of the test for diagnostic purposes. If the protein curve simply follows the acid curve, it merely represents the action of the gastric juice on the bread ingested, and may be taken as an index of gastric function. This is already given in the acid curve. But abnormal or pathologic possibilities exaggerate the curve out of all proportion to the acid curve, either in the very beginning, during, or at the termination of the curve. Therefore, if bread alone can only give us a definite amount of protein within a definite time, an exaggerated quantity or the presence of high figures must mean that the protein comes from other sources than bread. In the present work, the separation and recognition of the different forms of protein has not seemed practical for routine work. The method of interpretation has been based on a comparison of the acid and protein curves. It is therefore perfectly evident that a certain protein concentration in a given time can be produced from a standard meal. What are the extrinsic sources of protein? These may be (1) blood; (2) the presence of pus either intragastric in origin or swallowed; (3) the end-products of protein digestion still in the stomach through atony or obstruction; therefore stasis, lack of motor tone or actual obstruction may unduly increase the protein concentration, all of which are removed by emptying the stomach before administering the meal; (4) a possible exudation of lymph or serum from ulcer; (5) the exudation from a malignant lesion. These factors should be borne in mind in interpreting the findings. In Cases 2, 8, 1, 10, 13, the findings indicated the absence of ulceration, and the subsequent course of the cases demonstrated the correctness of our diagnosis. In Case 14 the curve indicated strongly the presence of ulcer which would cover all the symptoms of the case. In Case 24, the diagnosis of neoplasm was definitely eliminated on that finding and subsequent events justified the diagnosis. In Case 27, it is evident that an achylia could not produce such a curve unless an added factor such as the ulceration of a neoplasm came into play. In conclusion, we may state that while we do not claim any pathognomonic value for the test, we de believe that it will add another link to the chain of evidence which may decide for or against a given diagnosis.

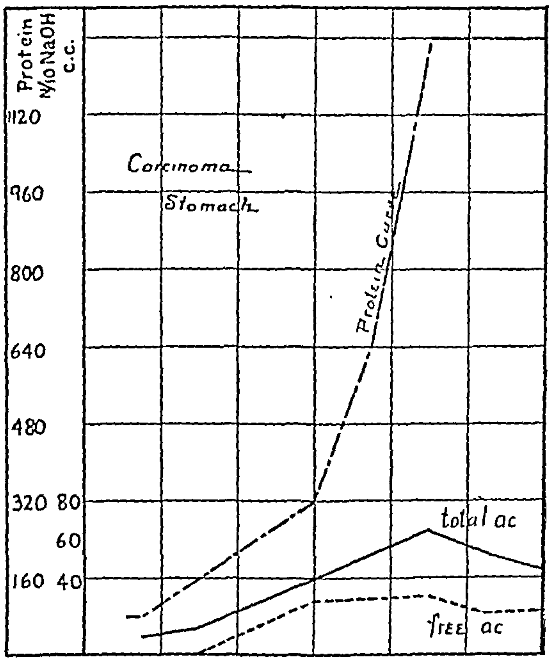

Chart 5.—Protein, total acidity and free acid curves in case of gastric carcinoma.

CONCLUSIONS

1. The gastric juice in health shows definitely a protein content of very low degree.

2. This content is increased in disease by the addition of an exudation of protein material from inflammatory, ulcerous, or carcinomatous mucous membranes, or by the addition of partially digested and retained food residues, or the swallowing of protein material such as certain forms of sputum.

3. Bread and tea alone, following the composition of the Ewald meal, will show in the absence of any pathologic factor a definite amount of protein corresponding to the curve or the digestive power of the juice secreted. A mixture or maceration of bread in tea will show a protein content on 1:20-1:40; if the mixture is acted on by an artificial gastric juice in vitro the protein content of the juice rises steadily within the next two hours and may reach 1:320 in seventy-five minutes. In other words, there is a transformation and liberation of soluble protein which may be demonstrated by the Wolff technic.

4. The pathologic significance arises when a curve shows any marked deviation from this recognized standard, that is to say, when there is an undue concentration of protein out of all proportion to that normally found at that particular phase in digestion. *If therefore a marked increase in protein does not conform in a general way to the acid curve it can be definitely stated that the protein is coming from other sources than the proteins of the bread.*

5. An analysis of the protein would seem to demonstrate that normally it is of the nature of a proteose, but in inflammatory or ulcerative conditions it is probably serum protein removed to a large extent by saturation with ammonium sulphate.

6. We could call attention to the interesting curves found in ulcer, many of which showed traces of blood, several of which can be explained on the basis of protein retention, some of which must be explained on the basis of hypothetic exudation.

7. In the differentiation of achylia and carcinoma, we pointed out that the test was of value in direct proportion as the case approached a true achylia and the added factors (extrinsic) such as swallowed pus, bleeding and protein residues could be ruled out. We likewise pointed out that the one-hour point was insufficient for examination and that the characteristic for carcinoma in these cases is a divergence of the protein curve out of all proportion to the acid curve. Infected catarrh, hemorrhagic erosions, achlorhydria, hemorrhagica gastrica, may give high findings, but they do not have the tendency to give a steadily increasing protein content.

8. We believe that a study of the protein curve may yield information of the greatest value, provided that all the precautions have been observed.

Spring Tonics.—The idea that a "tonic" is needed in the springtime is a mere tradition. Most of such tonics sold to the public are strongly alcoholic, and may prove distinctly harmful.—Health Letter, Life Extension Institute.

THE DIAGNOSIS AND TREATMENT OF INFECTIOUS ENDOCARDITIS

GEORGE E. EBRIGHT, M.D.
SAN FRANCISCO

Since the researches of Poynton and Paine about fifteen years ago which resulted in the isolation of an infectious agent of acute rheumatism, much has been accomplished to elucidate the etiology of infections of the endocardium. Particular interest attaches to the work of Billings, who in 1909 isolated what appeared to be an attenuated pneumococcus in slow endocarditis. Schottmüller,[1] in March, 1910, gave the name of endocarditis lenta to a group of cases which appear to be the same as those described the year before by Billings as due to an organism to which he gave the name of *Streptococcus viridans* on account of its growing with a greenish color on agar. Publications by Libman and Cellar in March of the same year added further interest to this type of endocarditis and it remained for Rosenow[2] to harmonize the bacteriology of the subject by demonstrating that by varying the oxygen pressure in culture mediums the organisms which are frequently the cause of arthritis and endocarditis may be changed culturally and morphologically from one to the other. Rosenow[3] describes three strains of organisms which he changes one from the other, each of which has a marked affinity for certain structures, one hemolytic streptococcus with affinity for the joints, *S. viridans* with affinity for the heart valves, and *S. rheumaticus* which again has a predilection for the joints.

Weight of authority now compels the recognition of that form of chronic infectious endocarditis due to the viridans group as a distinct entity of which there are three types.[4] First, that in which patients develop nephritis and die of uremia. Secondly, that in which is recognized chronic endocarditis with fever, the patients having large valvular lesions, occasional petechiae of the skin and other embolisms, joint symptoms, more or less anemia with a pale skin or more or less pigmentation. Thirdly, that in which the striking feature is a diffuse brown, sometimes quite dark color of the face and some pigmentation on the rest of the body, with more or less anemia, usually palpable spleen and tenderness of the sternum. Baehr[5] describes as characteristic of endocarditis lenta, lesions of the kidney due to septic emboli giving a distinct pathologic picture.

In addition to the viridans group other bacteria may cause endocarditis. Staphylococcus infections[6] may be usually traced to some skin infection —furuncles or felon or some injury to the mucosa as in catheter fever; suppurative metastases are common. Pneumococcus endocarditis may occur with pneumonia; gonorrheal endocarditis is not uncommon. Endocarditis due to influenza has been described by McPhedran[6] and others. Endocarditis may be caused[7] by the meningococcus as a primary lesion. Nankivell[8] describes a case in which he isolated a diplococcus not elsewhere described as a cause of endocarditis. A capsulated Gram-staining diplococcus occurring in chains was isolated by W. H. Smith.[9] Lamb and Paton[10] reported a case of vegetative endocarditis caused by a spirillum. It is to be observed that children under 4 years of age are apparently immune to chronic infectious endocarditis.[11]

Endocarditis may be secondary to articular rheumatism, tonsillitis, pyorrhea, septic endometritis, pyogenic inflammation of the skin and mucous membranes. Experimental appendicitis having been produced with the Poynton and Paine organism would make it appear possible that appendiceal inflammations may figure as a precursor to endocarditis. Endocarditis may follow an acute gastro-intestinal infection. It is, however, difficult in some cases to say whether the cardiac inflammation is secondary to enteritis or whether the abdominal symptoms are not purely toxic in nature from a primary endocardial invasion. There remain further many instances of acute endocarditis in which no discernible lesion has preceded the involvement of the endocardium.

It has been shown in the chronic infectious type of endocarditis[12] that the beginning lesions are subendothelial bacterial embolisms. The valve leaflets being relatively poor in vascularity, the bacteria may grow faster than the leukocytes are able to cause their destruction; there results hemorrhage and the formation of vegetations going on to ulceration. There must be recognized the possibility of resolution before the stage of advanced vegetation formation is reached, as Libman described hearts in which there may be seen areas of active inflammation with other areas where inflammation has subsided with resulting scars. There is no doubt that in fortunate instances, such an inflammation of the valves as may give rise to very definite physical signs may still recover without such scars as result in the impairment of the valve function and, sooner or later, cardiac decompensation.

Leukocytosis, as a rule, will not be found before the stage of ulceration and may not be present when large numbers of bacteria are in the blood.[13] While there may be sufficient inflammation to cause fever and sufficient symptoms to render the patient ill and sufficient endocardial change to give rise to definite physical findings, there may still not be great enough intoxication to call forth a leukocytosis.[13]

It is to be recognized that simple endocarditis differs only in degree from malignant endocarditis, both being of an infectious nature, and that a mild endocarditis may of course become malignant. When such a series of hearts is considered as those which Libman demonstrated in which healing of quite considerable endocardial inflammation has taken place, much encouragement is afforded in the treatment of rather well-marked cardiac inflammations, in which, however, ulceration has not yet taken place nor can bacteria be demonstrated in the blood stream. The following cases are illustrations in point.

Case 1.—A previously healthy child, 7 years old, of good family history, complained on the completion of a transcontinental journey, of a slight fever and indisposition. She was seen first two days later after the fever had disappeared, the child not having regained her wonted spirits. On examination she appeared rather pale and apathetic. Physical examination showed normal conditions except the heart; its action was *forcible and rapid*, pulse rate 120 a minute, regular, no cardiac enlargement, left margin extending to the left of the nipple line. There was a soft systolic murmur with the sound at the apex, and a soft systolic murmur at the pulmonic area. The throat, skin, mucous membranes and joints were normal, leukocytes 4,000, red cells 5,000,000, the urine was normal, no red cells.

The following day the heart had dilated so that the left margin was 1½ inches outside the left nipple line, the pulse rate had dropped from 120 to 82 a minute with marked irregularity due apparently to extraventricular systoles. Every second, third, fourth, fifth, eighth and tenth successive impulse the beat would be missed at the wrist, the average being a dropped beat for every fourth impulse. This irregularity continued with gradual improvement so that by the end of the next forty-eight hours the left margin of the heart was only ¼ inch outside the left nipple line and the pulse at times was regular. By the end of four weeks with gradual improvement the pulse was practically regular. During the next two weeks, however, skipped beats occurred about half the time. During the fifth week irregularity occurred again, the average being five beats dropped in a minute, then regular again for three weeks when an average of six beats was dropped in a minute during the course of one day. Again a period of regularity for a week when two days occurred in which from four to six beats would be dropped in a minute at times. From then on until the end of the seventh month the pulse remained regular. The temperature throughout showed physiologic variations; cardiac murmurs varied more or less from time to time depending largely on nervous influences. The patient was kept rigidly horizontal in bed. The pulse rate for the first three weeks was rather low, that is between 68 and 100, after averaging about 100 a minute, ranging from 80 to 110, but as a rule in the neighborhood of from 100 to 104.

Convalescence was otherwise uneventful except that about a week after the onset of the illness a sudden pain in the calf of one leg suggested an embolus; this, however, subsided and there were no further embolic symptoms; by the end of seven months the heart was normal in size; that is, just at the nipple line or within it, the heart sounds perfectly clear and the rate regular. The child was kept in a horizontal position as quiet as possible for five months. During that time there were systolic murmurs heard at the pulmonic and mitral areas, the pulmonic murmur persisting much longer than the mitral. For many weeks a little excitement or exertion caused a reappearance of the mitral bruit. At the end of the fifth month, the heart being normal in size and the mitral sound being clear, she was allowed to sit up in bed five minutes; the following day there was some dilatation and increase of the murmurs. These disappeared in the course of a day or two. At the end of the month she was sitting up in bed two hours a day with rubs and passive exercises. Between the latter part of the fourth and sixth months, the murmur to the left of the sternum in the second interspace, heard when the patient was in a horizontal position, disappeared if she were held in a sitting posture.

General massage was instituted when the heart had been found normal in size for about two weeks and the mitral sound showed a tendency to be pure. With each progressive step, whether massage or passive movement or sitting up in bed, the heart displayed marked irregularity so that these changes were made in very slow stages before the patient was allowed to sit unassisted even for a few minutes. She was held in an upright position as a test of the myocardial function and was not allowed to support herself until this maneuver was not followed by irregularity or too rapid pulse. At the end of the seventh month she was allowed every liberty except standing. The heart was normal in size and all the sounds pure. She was then allowed to go to the seashore for three weeks but not allowed to walk.

With the beginning of the eighth month a few were permitted, which resulted after three or four days in a rather severe dilatation of the left ventricle. This was associated with systolic and pulmonic murmurs and an occasional slight irregularity in the shape of a lengthened diastole. The heart recovered after a few days in the horizontal position. There was no further cardiac trouble and the patient's heart remains at present, after an interval of two years, without any perceptible hypertrophy, with perfectly normal valve sounds, and the child is without the necessity of restriction in her activities which are those of a normal active girl. The diagnosis in this case rested on fever, rapid heart action followed by rather acute dilatation and irregularity, together with murmurs that changed from time to time and very marked muscular irritability.

Case 2.—Acute endocarditis with aortic and mitral valvulitis in a boy, aged 14. On July 26, 1910, the patient complained of two large boils on his abdomen which had been untreated for some days and were exuding a large amount of rather thin pus. He did not complain of his heart, but on examination the left margin was found to be slightly outside the left nipple line. There was a systolic thrill felt at the fourth interspace over the heart, sharp accentuation of the pulmonic sound, soft aortic murmurs to the right of the sternum heard also in the left second interspace and a distinct systolic mitral valvular murmur. Subsequently these adventitious sounds varied in intensity. The pulse dropped two or three beats a minute, rate at first 86 to 90 a minute, leukocytes 7,400, temperature 98.4 to 99 F. During the course of the illness there was no evidence of emboli either in the skin, joints or kidneys.

During the second week there was a very questionable pericardial rub. The spleen was unchanged upward being, at the upper border of the ninth rib, not palpable. This patient was kept in bed until the murmurs disappeared and irregularity of the heart ceased. It was not until twelve months later, and two or three weeks after he was permitted to be on his feet, that he was allowed to walk down stairs. During that time his illness was very similar to that of the patient in Case 1; he had been allowed to sit up in bed as soon as the heart was normal in size and murmurs were absent. Passive exercise and massage were employed and exercise was allowed as soon as possible. With the advent of each new procedure whether massage, passive movements or sitting position, the heart became enlarged and missed beats and murmurs reappeared. He was not allowed to stand for long until none of these things happened, with the result that not only have the heart sounds remained normal but in particular there is no ventricular hypertrophy. At present, four years later, the patient is in perfect health. His life so far as violent exercise was concerned was restricted for a year, but aside from that has been allowed every liberty including the usual collegiate activities, and during his vacations has become an expert cowboy on a cattle ranch.

Case 3.—Acute endocarditis with mitral valvulitis in a girl aged 7½. The mother had died of infectious endocarditis. Child's previous health had been normal. The onset of illness consisted of loss of appetite and slight malaise. Physical examination showed the left heart dilated, pulse regular, rate 110, no fever, but a distinct systolic murmur at the pulmonic and mitral areas. The murmurs varied during the next few months, the mitral murmur gradually diminished until it finally disappeared; pulmonic murmurs persisted about ten months. The heart was normal in size in three or four weeks. The patient's recovery was complete in ten months of which eight were spent in bed. Two months later she was allowed to return to school, the heart being normal in size, pulse regular, valve sounds perfectly pure. In this case there was no leukocytosis, no evident emboli. Normal health has been maintained for three years, during which time there have been no restrictions on her activities. There is no evidence of hypertrophy of the heart.

In these three cases there was at no time leukocytosis; a blood culture was made several times in the instance of the boy, with negative results, and in none was there more than a very slight fever; the pulse was variable. With the onset of the inflammation it is interesting to observe that there was tachycardia in one case for a day before dilatation occurred. Dilatation of the ventricle occurred suddenly and was associated with a slow intermittent pulse.

In the matter of treatment, the ultimate result to be expected in any case would depend largely on the degree and virulence of the inflammatory processes. It is advisable to reduce the work of the heart to a minimum by means of absolute rest, regulation of diet with a view to preventing distention of the stomach and colon and eliminating as much as possible a rise of blood pressure by the avoidance of hearty meals, use of the ice-bag, etc. The matter of rest is the most important of all. In fortunate cases this will result in a short time in diminution of the cardiac dilatation and will bring about conditions that most favor the subsidence of the inflammation. It is to be borne in mind that rest must be carried out with the utmost rigidity and the patient left as much as possible to the care of a suitable nurse. It is seldom desirable to separate a child from its parents, but the fewer people that enter the room the better. During the stage when inflammation is still present passive movements and massage have no place in the treatment. These measures, however, are of benefit when it is felt that the inflammatory process has disappeared and the myocardial irritability has sufficiently subsided.

The great aim in the treatment of such mild cases as here detailed is to prevent the increase of cardiac inflammation to such a point that there is the full painted picture of infectious endocarditis with its hopeless prognosis, and also to obtain a recovery before inflammation of a valve has gone to the point of such destruction as will result in scars of the valve segments and sooner or later a cardiac cripple. To that end it must be insisted on that the patient remain in bed a sufficient length of time, and a safe minimum is three months. Broadbent points out that a child with endocarditis dies, as a rule, before it attains adult life, especially if it does not receive that care which insures a complete subsidence of the inflammation, which may smolder for months, and a return of the heart to its normal size, also until the myocardium has lost its abnormal irritability and has regained such a sufficient margin of reserve strength as will prevent dilatation on slight provocation and will enable it to bear the burdens that a careless person may impose on it. Experience seems to teach that in adults acute endocarditis complicating inflammatory rheumatism is in many instances a very benign disease, recovery taking place in a much shorter time than is the rule with children. Valves already injured by previous inflammations present greater obstacles to a cure than inflammations occurring for the first time.

The use of vaccines is not unattended with danger.[14] In the first place the patient is already generating toxins theoretically sufficient without the addition of artificial vaccines. Again, when large numbers of bacteria are found in the blood, the use of vaccines may be attended with a reduction of the number of bacteria by destruction, but there are liberated at the same time toxins which result in an increase of the leukocytes and fever and a lowering of the condition of the patient. The same thing results in the use of foreign serums. It appears that the invading organism immunizes itself against the antibodies in the blood of the patient so that when foreign serum is introduced, although the number of bacteria may be diminished, the net result for the patient is bad. The use of cardiac stimulants is unnecessary so long as the proper amount of cardiac work is being performed, and it would seem rather advisable as long as possible to avoid stimulating the myocardium, already more or less degenerated from bacterial poisons, as the great desideratum is cardiac rest, not work. It is not to be denied that the use of small doses of digitalis may become necessary, but it will be observed that the heart muscle in endocarditis is very susceptible to the action of stimulants and even small doses of digitalis, for instance, may produce an irregularity before not present and which disappears on the cessation of the drug. Not only that, but in the presence of vegetations stimulation may cause a dislodgment and troublesome embolus.

INTESTINAL OBSTRUCTION DUE TO SIGMOID VOLVULUS

WITH REPORT OF A CASE OCCURRING IN A CHILD

ALEXIUS McGLANNAN, M.D.
BALTIMORE

In December, 1912, I reported a study of 191 cases of intestinal obstruction, exclusive of external hernia.[1] This series included 8 cases of sigmoid volvulus, all occurring in adult patients. Since that time I have added to the original group the records of 66 cases of intestinal obstruction, making the present number 257. Among the new cases is one of sigmoid volvulus occurring in a child of 6 years, which is herewith reported.

Acute obstruction is much more common in the small than in the large intestine, 201 to 56 being the proportion in this series. Volvulus of the sigmoid occurred 10 times in the series, making about 18 per cent. of the large intestine cases, and 3.8 per cent. of all forms of obstruction. Volvulus of the small intestine occurred 11 times, twice in children. Of the 257 cases, 41 occurred in children under 12. Eighteen of these cases were ileocecal intussusception, and 6 intussusception of the small intestine proper. Intussusception therefore makes up more than half of all the cases occurring in children, and is 8 times as common as all forms of volvulus in this class of patients.

Volvulus of the sigmoid occurring in a child is an unusual form of obstruction. As is usual when the obstructing agent interferes with the circulation in the mesentery the symptoms are severe and toxemia develops very rapidly after the onset of the obstruction. Therefore the passage from the first to the third or terminal stage of the disease may require but a few hours of illness.

A true volvulus of the sigmoid is probably impossible unless this portion of the colon is redundant. In all the cases studied this enlarged sigmoid is noted. The normal contour and close position of the foot-points of the sigmoid make a mechanical arrangement especially favorable for the development of a twist when this loop of bowel is elongated. The feces collect in the loop, becoming more and more hardened as the constipation increases. Strong purgatives are usually administered to relieve this condition, and the resulting vigorous peristaltic movements forcing the contents of the distended loop of bowel against the fixed lower foot-point jam this outlet. Persistence of the force from above first makes the loop spastic and distended, and then sends the upper free portion in a spiral direction around the descending fixed portion.

---

[1] McGlannan, Alexius: Intestinal Obstruction, The Journal A. M. A., March 8, 1913, p. 733.

Constipation is not necessarily a forerunner of volvulus. Any violent peristaltic action may cause the spastic contraction and the twisting movement of the long sigmoid loop.

The symptom of onset in sigmoid volvulus is abdominal pain, usually severe paroxysmal cramps, with or without previous constipation. Tenesmus with an inability to pass anything by rectum, except perhaps a little mucus, is often a secondary symptom. Blood may be present in the material expelled but the quantity is small and this sign is not at all frequently observed — a point of difference between the symptoms of volvulus and those of intussusception. An enema may be effectual, but if this does not relieve the pain or the nausea and vomiting which come on in a few hours after the onset, operation is indicated. The enema should be given through a long tube and with the patient in the knee-chest position.

The leukocytes are rapidly increased in number, reaching 25,000 or more in a few hours. In the 8 cases in adults studied the average was 23,000, the extremes 13,000 and 40,000. In the case occurring in a child the leukocyte count was 41,500.

Later on there will be distention with visible peristalsis, a palpable spastic coil in the lower abdomen, and then toxemia.

Operation should be performed in the early period of the obstruction, when it is safe to remove the redundant sigmoid and in this way prevent recurrent attacks. Simple relief of the volvulus is very likely to be followed by a recurrent obstruction. In one case of this series the patient had 32 attacks of obstruction and 3 laparotomies before his giant sigmoid was removed and a permanent cure effected.

The history of the case occurring in a child is the following:

The patient, a white girl, aged 6, was admitted to the children's ward of Mercy Hospital and examined in consultation with Dr. Edgar Friedenwald, who had at once recognized the acute surgical abdomen. The history was of two days' illness, the onset with cramps and diarrhea, followed by vomiting and tenesmus. No blood was in the movements. The patient was an anemic child, toxic, extremely listless, pulse rapid and thin; respirations thoracic and shallow. The abdomen was generally distended and tender. Muscle spasm and rigidity most marked in right lower quadrant. Dulness in both flanks. White blood count, 41,500, polynuclears 91 per cent.

Operation was performed immediately under novocain infiltration and ether anesthesia. A long right rectus incision was made. When the peritoneum was opened a large quantity of straw-colored fluid poured out. The small and large intestines were distended, but not inflamed. A hasty exploration of the right iliac fossa showed a healthy appendix and a greatly distended cecum. A much dilated loop of large bowel extended from the left over into the right lower abdomen. This loop was followed into the left fossa and proved to be the fundus of a sigmoid volvulus, which had twisted on its foot-points through an arc of about 300 degrees. This was untwisted, and a rectal tube passed through the anus by an assistant was guided by a hand in the abdomen up into the dilated loop. There was an immediate expulsion of gas and watery feces through the tube, with relief of the distention of the bowel. The abdomen was closed in layers, using fine silk sutures. The stomach was washed out and an ounce of castor oil given through the tube. Five hundred c.c. of salt solution and one dose of 1/200 grain atropin were given subcutaneously.

The patient was quite toxic for the first twenty-four hours after the operation and lavage of the stomach was required. After this time she improved steadily and in ten days was out of bed, the wound having healed.

Six weeks after the relief of the obstruction the second operation of resection and anastomosis was performed for the removal of the redundant sigmoid. The divided ends of the bowel were turned in and the anastomosis made by the method described by Bloodgood.[2] The turned in ends were sutured outside the parietal peritoneum and drains carried down to them. The muscles, fascia and skin were closed up to the drains.

Leakage from one end of the bowel occurred on the fifth day and prevented primary healing. The sinus closed spontaneously on the twenty-second day and the wound healed tight a week later.

As the child's home surroundings were very poor, she was kept in the hospital a month after the wound had closed. During this time she spent the days on the roof garden and was given increased nourishment. Her bowels moved daily without cathartics, her digestion was unimpaired and on her discharge she was in perfect health.

114 West Franklin Street.

GASTRIC AND DUODENAL ULCER

THE INFLUENCE OF OPERATIVE PROCEDURES ON GASTRIC MOTILITY AND SECRETION *

WALTER W. HAMBURGER, M.D.
AND
JAMES J. LEACH, M.D.
CHICAGO

It is generally conceded, both clinically and experimentally, that among the various factors responsible for chronic ulcer of the stomach, motor insufficiency and hypersecretion play the leading, if not the title, rôle. It follows that, in the treatment of ulcer, therapeutic procedures should be devised to control, so far as possible, these two important factors; in fact, the value of a given therapeutic measure can in a certain sense be gaged by its ability to restore the normal emptying time of the stomach (or to increase it) and to diminish the hyperacidity of the gastric contents.

Among various therapeutic measures instituted for the cure of gastric and duodenal ulcer, surgical procedures have been inaugurated in constantly increasing frequency. These surgical procedures are legion; they possess inexhaustible variations and modifications; they are constantly being supplanted by new models and new styles. Scant inquiry is devoted to the ultimate results of these operations, little thought to the permanent relief of symptoms, to the healing of the ulcer and the prevention of recurrences, and no consideration to gastric function, particularly gastric motility and secretion.

The present paper is a preliminary study of the postoperative results in a series of gastric and duodenal ulcers, with particular reference to the effect of operations on gastric motility and secretion, and the value of the procedure as gaged by these standards.

---

[2] Bloodgood: Ann. Surg., 1909, xlix, 161.

* From the medical and surgical services of the Michael Reese Hospital. Read at the first meeting of the Chicago Society of Internal Medicine, Feb. 22, 1915.

A few similar studies have been made. Wilcox,[1] in 1909, reported one of the earliest postoperative studies, finding in general that stomach acidity, particularly "active" hydrochloric acid, diminished regularly after gastro-enterostomy.

Schüller,[2] in 1911, in a comprehensive study of forty clinical cases from Leube's clinic, as well as experimentation on animals, concluded that gastro-enterostomy alone, and gastro-enterostomy plus pyloric resection, modified motility more than secretion. In cases of pyloric obstruction with motor insufficiency, gastro-enterostomy alone raises the emptying time to normal, *but does not increase it beyond.* (In one case the emptying time was delayed.) In cases without obstruction and good motility, gastro-enterostomy produced no change, the emptying time remaining normal (no increase). These results are different from those of Jonas, Steindel and others, who describe the emptying time increased above the normal in all cases of gastro-enterostomy. They likewise differ from the results of Hartmann and Soupault, Rosenheim, Dunin and others, who find the emptying time delayed or made worse.

In fifteen cases of the combined operation (gastro-enterostomy plus pyloric resection), Schüller found the motility of the "pylorus frei" stomach inconstant in different patients, and in the same patient at different times. With complete removal of the muscle-bearing portion of the stomach (antrum pylori), insufficiency is liable to occur, because of increased difficulty of overcoming strong jejunal peristalsis.

In reference to secretion, Schüller found rather universally the values of free and total acidity lower than before operation, similar to the conclusions of Krause, Renki, Kausch, Hartmann and Soupault, and others. A few cases showed no change in acid values. One patient with normal acidity before operation showed a constant postoperative hyperacidity. He noted no striking difference in acid values in gastro-enterostomy, with or without pyloric resection.

Dogaero,[3] in 1913, came to somewhat similar conclusions. He estimated the emptying time of the dog's stomach by use of gastric and duodenal fistulas after introducing a 5 per cent. solution of glucose. In dogs with complete pylorectomy and gastro-enterostomy, the stomach discharged its contents much more slowly than normal. A mixed dietary made this motor delay even more apparent. He concluded that the pyloric portion normally acts as an accelerator, and that in its absence (pylorectomy) the pendulum contractions of the jejunum act as a resistance to the relatively weak fundus musculature.

Faulhaber and Redwitz,[4] in 1914, analyzed twenty-six cases of penetrating callous ulcer of the fundus, in which a resection of the ulcer-bearing median portion of the stomach with direct union of the cardial and pyloric stumps had been made by Enderlen—the "sleeve" operation of American surgeons. In from sixteen days to two years following operation, the patients were submitted to a complete physical examination, test meals, fluroscopic and Roentgen-ray examinations, etc. All had gained in weight, had taken up their old occupation and could stand all foods in moderate quantities. Test meals showed free acid and total acidity markedly lowered; some even were subacid or anacid. Fluoroscopy showed early emptying time increased in all cases, although complete emptying time was variable—the early rapidity being only temporary. They found no constant relation between emptying time and secretion; for example, cases with most rapid emptying time had relatively high acidity. They concluded that the motor activity of the pyloric antrum and the sphincter was not disturbed by resection of the middle portion of the stomach, and that the time of emptying depends on the balance between the relatively inactive fundus and the active antrum.

The cases forming the basis for this study comprise seventeen—nine gastric and eight duodenal ulcers. With the exception of three private cases of one of us (Hamburger), these patients were obtained from the regular medical and surgical services of the Michael Reese Hospital. The patients either presented themselves voluntarily because of nonrelief from their operation, or came in response to follow-up letters. Of the seventeen patients, eight received no or only partial relief from their complaints; nine cases resulted in marked benefit or complete cure. The patients were examined for the most part on an average of from three months to two years following operation; one patient as early as five weeks, one as late as twelve years. So far as possible, all patients were submitted to complete physical examination, test breakfast and motor meal, fluoroscopy and Roentgen-ray examination before and after operation. The roentgenographic examinations were made under the supervision of Dr. Frances Turley. In some instances this complete examination was impossible; in a few cases we were forced to be content with only partial data, and in two cases letter replies constituted the only available information.

The gastric ulcers divide themselves into two groups: lesser curvature ulcers (four) and pyloric ulcers (five).

The following may be taken as a type of the former:

Case 1.—S. W., merchant, aged 49 years, had a gnawing pain in the epigastrium one hour after eating for thirteen years and vomiting for two weeks. He had lost 15 pounds in weight. He was a heavy smoker and ate hurriedly. He had had chronic rheumatism twenty years previously. Physical examination was negative. Ewald's test meal revealed:

Amount	Free	Total
60	20	40
90	25	43
90	20	45

Motor meal was negative (seven hours). Fluoroscopy revealed the stomach completely empty in four hours. Roentgenoscopy revealed a penetrating ulcer of the lesser curvature.

The ulcer was excised near the cardia. No gastro-enterostomy was performed. Five weeks after the operation, examination revealed:

	Amount	Free	Total
Ewald's	190	0	10
Motor meal	40	30	90

Fluoroscopy revealed the emptying time at six hours, and roentgenoscopy a partial hour-glass constriction.

Nine months after the operation the patient wrote: "Now I eat practically everything, including meat; eat more than used to before operation; have no pain; have a better appetite; no vomiting; have gained in weight."

Epicrisis: Excision without gastro-enterostomy. Clinical result excellent. Motility: Slight motor insufficiency (hour-glass) (tube and fluoroscopy) immediately after operation, probably only temporary. Secretion: Slight increase in amount—decrease in degree of acidity. Postoperative hypersecretion?

---

[1] Wilcox: Quart. Jour. Med., 1909, iii, 93.
[2] Schüller: Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1911, xxii, 715.
[3] Dogaero: Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, 176.
[4] Faulhaber and Redwitz: Med. Klin., 1914, Nos. 16 and 17.

Of the three remaining ulcers of the lesser curvature, one had gastro-enterostomy with excision; two, gastro-enterostomy alone. All patients obtained a fairly satisfactory clinical result, those with excision the best. In all, secretion values were reduced. Motility was more complicated: 1, normal before—slight delay afterward (excision alone); 1, slight delay before—normal after operation (excision plus gastro-enterostomy); 2, normal before—normal after operation (gastro-enterostomy alone).

Results agree fairly well with Schüller, and parallel the conclusion of Bolton[5]:

> "If stomach empties in normal time, gastro-enterostomy must be a useless procedure; operation would prove useless in treatment of an ulcer situated away from pylorus, either on lesser curvature or elsewhere."

The five pyloric ulcers are more difficult to handle. The following is an extremely brief summary of their —in some instances—extremely complicated histories:

CASE 2.—E. S., salesman, aged 48, had had a burning and gnawing pain one-half hour after eating for five years, and delayed vomiting. He had lost 40 pounds in weight. He had had typhoid twenty-seven years before.

Examination revealed an ulcer at the lesser curvature near the pylorus with marked pyloric obstruction; marked stasis with hyperacidity.

The operation consisted in resection of the ulcer-bearing portion, pylorectomy and gastro-enterostomy.

The result after ten months was excellent. The stasis was relieved. The emptying time was three hours. Tube and fluoroscopy were in accord. The acidity was reduced.

The positively good result in this case is in marked contrast to the following:

CASE 3.—A. C., blacksmith, aged 38, had had a burning pain two and one-half hours after eating for two years. There had been vomiting for two weeks. He had lost 12 pounds in weight. He had had typhoid fifteen years before.

Examination revealed an ulcer of the pylorus, with adhesions; marked stasis, with hyperacidity.

A posterior gastro-enterostomy was performed, the pylorus not excluded.

The result after six weeks was improvement. The stasis was improved (the stomach being empty in seven hours). Hypersecretion remained, and the acidity was the same.

In this case the motility result was better than the secretion, although the patient was not observed sufficiently long to be sure of the permanence of the result. Pylorectomy or pyloric exclusion should probably have been performed, in addition to gastro-enterostomy. There was probable postoperative hypersecretion.

CASE 4.—B. K., cigarmaker, aged 42 years, had had epigastric pain two hours after eating for eight years, with constant vomiting; loss in weight.

Examination revealed marked stasis, marked hypersecretion and hyperacidity. There was an old pyloric ulcer, with pyloric obstruction.

A posterior gastro-enterostomy was performed; the pylorus was not excluded.

The result was poor. The pain, vomiting and stasis were unrelieved. Gastric tetany, one month. Roentgenoscopy revealed a vicious circle. Stasis and hypersecretion were made worse.

A second operation for adhesions, with lateral anastomosis entero-enterostomy, resulted in improvement for three years. The result after three years was poor. There was complete obstruction, neither the pylorus nor the stoma functionating.

Epicrisis: No relief from gastro-enterostomy. Ulcer should have been resected and pylorus closed.

CASE 5.—A. W., aged 48, had had pain after eating for three and one-half years. There were no obstruction, hyperacidity or positive surgical indications.

Examination was negative.

Operation revealed adhesions and a scar at the pylorus. A gastrojejunostomy was performed, with no relief from symptoms. There was conversion of normal motility and secretion to stasis and hypersecretion.

Fluoroscopy revealed normal motility; motor meal, stasis.

A second operation for adhesions, with pyloric exclusion, resulted in the patient's feeling well for five months.

Epicrisis: Surgical interference not indicated. Patient had not had benefit of medical treatment. Conversion of normal stomach function into abnormal. No permanent relief from first or second operation.

From this series the following conclusions may be drawn: Gastro-enterostomy performed without definite surgical indications (stasis—hypersecretion) is liable to convert normal gastric function into abnormal. Gastro-enterostomy with definite surgical indications is liable to fail and increase stasis and hypersecretion if the pylorus be not excluded. The best results, with relief of stasis and hyperacidity, are obtained by pylorectomy (or pyloric exclusion) plus gastro-enterostomy. In the case of pyloric ulcer, excision and closure are of even greater importance than in ulcer of the lesser curvature. Conversion of normal to abnormal function is due to pylorospasm (Hertz[6]) or postoperative hypersecretion, or both. In the latter event, some cases evidence good motility, but show marked hypersecretion following the test breakfast and motor meals.

Postoperative hypersecretion (without stasis), as observed in this series, as well as in several duodenal ulcers, to be discussed later, has several interesting problems. From a clinical standpoint, it is likely that in cases showing acid contents after motor meals, the explanation lies not, as has been thought, in postoperative stasis, but in postoperative hypersecretion. Furthermore, postoperative hypersecretion may explain certain discrepancies found to exist between the results of bismuth-buttermilk meals, as observed by the fluoroscope, and motor meals, as determined by the stomach tube. In fact, in two cases the bismuth meal left the stomach within six hours, while the stomach tube at the end of seven hours yielded but 2 to 3 ounces of acid contents, with little or no food residue.

The physiologic mechanism of postoperative hypersecretion is described somewhat by Lobassow and Orbeli.[7] In certain operations on the dog's stomach, for example, the Heidenhain-Pawlow small stomach operation, they describe a hypersecretory postoperative period. This period of hypersecretion is usually transitory and is held to be due to increased irritability of the nervous control of the secreting glands, a result of operative trauma. Orbeli found a similar hypersecretory condition after making a simple stomach fistula. It is our belief that a similar postoperative hypersecretory period follows surgical procedures on the human stomach, and may account for certain postoperative findings. The thought occurs that postoperative hypersecretion may follow operations on other portions of the gastro-intestinal tract, such as appendix or gallbladder, or from narcosis alone. We hope to test this question out in the near future.

ULCER OF THE DUODENUM

Without giving separate protocols of the eight duodenal ulcer cases, we shall confine our discussion to several points which their study has brought forth.

1. Two cases of gastro-enterostomy without pyloric exclusion showed rapid (two-hour) discharge of bismuth up to and by way of the gastro-enterostomy opening, with delay (six hours) of food beyond the opening—the bismuth finally passing out through the pylorus. This was true of the motor meal plus bismuth, as well as the regular bismuth-buttermilk meal. In one case, the delay of the contents beyond the opening amounted to a true stasis. Another case showed rapid early discharge up to the level of the opening, but delay of the residue in the small sac below the level of the gastro-enterostomy opening. Placing the patient in a recumbent position allowed this residue to discharge.
2. As in the case of gastric ulcer, pyloric exclusion plus gastro-enterostomy was attended by the best results. In two cases with the pylorus left patent, marked stasis occurred in the overfilled and distended duodenum at the site of the ulcer! In this case, in spite of the wide, well-placed enterostomy opening, the maximum discharge occurred through the patent pylorus.
3. Cases with normal preoperative findings developed postoperative stasis and hypersecretion, similar to gastric ulcer.
4. Two duodenal ulcer cases showed late — four and twelve years, respectively — gradual closing of the gastro-enterostomy opening, necessitating a second anterior operation. Zweig[8] and Mallory[9] describe cases of spasm of the opening, similar to pylorospasm.

SUMMARY

1. Operative procedures on stomachs with normal motility and secretion frequently produce stasis, hypersecretion or both.
2. Stasis may be caused by pylorospasm, by contents stranded below the level of the gastro-enterostomy opening, or by contents held between the opening and the pylorus.
3. Hypersecretion may occur coincidentally or secondarily to stasis, but also independently, as a true postoperative hypersecretion, similar to the same conditions in dogs. This hypersecretory period is probably due to operative trauma, and is likely to be temporary. Postoperative hypersecretion explains certain discrepancies between bismuth and motor meal findings.
4. Operative procedures on stomachs with delayed motility and hypersecretion usually reduce motility to normal (but not beyond), and lower hyperacidity. This is particularly true if the pylorus is closed. If the pylorus is left patent, vicious circle, stasis in duodenum, spasm or secondary contracture of the opening are liable to continue the abnormal gastric function or to increase it.
5. Nonrelief from surgical interference in gastric and duodenal ulcer is due to (*a*) lack of properly placed surgical indications; (*b*) lack of thorough and prolonged preoperative medical treatment; (*c*) failure to devise the proper surgical procedure to meet the individual case, and (*d*) lack of prolonged *post*operative medical treatment.

SOME SURGICAL EXPERIENCES AMONG INDIANS OF ALASKA

EMIL KRULISH, M.D.
Passed Assistant Surgeon, U. S. Public Health Service
JUNEAU, ALASKA

Every physician at some time during his career is called on to administer aid and even to perform a serious operation under most trying circumstances, and without proper equipment and assistants; in this respect the following experience may be of some interest.

It has been estimated that at least 20 per cent. of the Indian children in Southeastern Alaska are afflicted with adenoids and diseased tonsils which require surgical interference. This condition is largely due to the rainy weather which prevails in this section of Alaska. During a recent tour of inspection of the Government Indian Schools in Southeastern Alaska, I performed fifty-seven surgical operations in thirteen days at Klawock and Hydaburg, two Indian settlements 40 miles apart on Prince of Wales Island.

LIST OF OPERATIONS

Hydaburg:		
January 14	1	pterygium
January 15	3	adenoids and tonsils
January 16	5	adenoids and tonsils
January 17	4	adenoids and tonsils
January 17	1	lipoma, weight 1½ pounds
January 18	7	adenoids and tonsils
Klawock:		
January 22	1	adenoids and tonsils
January 22	1	harelip
January 23	7	adenoids and tonsils
January 25	3	adenoids and tonsils
January 25	1	ectropion
January 26	4	adenoids and tonsils
January 27	4	adenoids and tonsils
Hydaburg:		
January 29	5	adenoids and tonsils
January 30	5	adenoids and tonsils
January 31	5	adenoids and tonsils
	53	
	4	other operations
	57	operations in 13 days

The table shows the maximum number of cases operated in a single day to be seven; five in the morning from 9 to 12, and two in the afternoon. The patients operated on for adenoids and tonsils were between the ages of 2 and 38 years; all operations were done under chloroform or ether anesthesia, and there were no fatalities or serious complications. But one case required resuscitative measures from the effects of chloroform, and a tonsil hemostat was applied in one case to check persistent hemorrhage.

The school house in each community was utilized for a hospital. One room served as an operating room and another as a receiving ward for postoperative cases, where they were kept for a few hours before being carried to their homes on stretchers. An improvised operating table was constructed from rough lumber and covered with blankets furnished by the patients. Sponges were prepared and sterilized by baking in an oven, while mercuric chlorid solution was used for the hands and towels and compound solution of cresol for instruments. As operating gowns were unavailable, a towel over the chest served as a substitute. The corps of assistants comprised a trained nurse to hold the tongue depressor, one teacher to light the oral cavity with a pocket electric flashlight and assist in sponging the field of operation, and a second teacher who administered the anesthetic under supervision.

The evening before the operation, and after a careful examination of the heart and lungs, each patient was given a dose of calomel, instructed to refrain from breakfast the following morning, and directed to bring two blankets and five towels for his individual use at the appointed hour. These instructions were very faithfully complied with and with two exceptions there was no vomiting during the operation.

I personally administered the anesthetic until the operative stage was reached, when the teacher continued it under close observation. The hands of the operator were immersed in bichlorid solution for a few moments, the head and chest of the patient covered with towels treated in the same solution, and the operation commenced.

The mouth gag being inserted in place and a tongue depressor holding the tongue off to one side, the tonsil was grasped by a forceps, dissected out, and enucleated with a snare. A forceps carrying a sponge was quickly introduced into the space formerly occupied by the tonsil and pressure applied to check hemorrhage while the anesthetic was resumed. The second tonsil was enucleated in the same manner, after which the adenoids were scraped with a curet and any remaining adenoid tissue completely removed with the index finger covered with gauze. The patient was then quickly turned over on the side to facilitate the expulsion of blood into a bucket on the floor. After all hemorrhage had ceased, the patient was cleansed and carried into the receiving ward on a cot, where the relatives applied cold towels about the neck and looked after him during vomiting spells. After each operation the instruments were washed off in water and thrown into the lysol solution, while the towels of the next patient were treated with bichlorid solution and the blankets arranged on the table.

This experience illustrates what can be accomplished under adverse conditions and without the facilities usually demanded by surgeons in hospitals.

Tincture of Iodin in First Aid Packet.—The Italian government has ordered thousands of small elastic rubber tubes to contain tincture of iodin. They are to be given the soldiers with their first-aid packet as an improvement over the tiny glass bottle of tincture of iodin and the brush given the French soldiers. The *Policlinico* adds that the British are said to be adopting the French method. In the Italian method the fluid is sprayed on the wound by pressure on the rubber tube.

EXTENSION OF THE LIMITS OF OPERABILITY OF RECURRENT CARCINOMA OF THE BREAST

CARL BECK, M.D.
CHICAGO

The operability of a carcinoma of the breast depends on many factors, chiefly, however, on the extent of the pathologic condition. It is true that many varieties of carcinoma exist as far as the malignancy and progress of the lesion are concerned. Some grow slowly, some rapidly, some form their metastatic deposits very gradually, others show from the start a quick dissemination. On the whole, however, the progress is similar in all, namely, first an invasion of the regionary axillary glands, then of the glands of the supraclavicular region of the same side, then of the chest and sometimes of distant portions of the body.

Experience shows that recurrence of the growth after a skilful radical excision is mostly seen in the axillary region and in the neck, whereupon the vessels, particularly the veins and the nerves of the arm, become blocked and compressed. The neuralgic pains of the arm and the edema of the same are for the most part the evidences of such a recurrence. When this stage is reached, most surgeons consider the case inoperable with the view of radical cure, and justly so, because it is very questionable that an elimination of the process now spread into a region of great vessels and proximity to the large nerve trunks is possible. The only thing to do in such cases is to comfort the patients with a Roentgen ray or Coley's serum and the most reliable morphin. Such cases are always a dread to the surgeon.

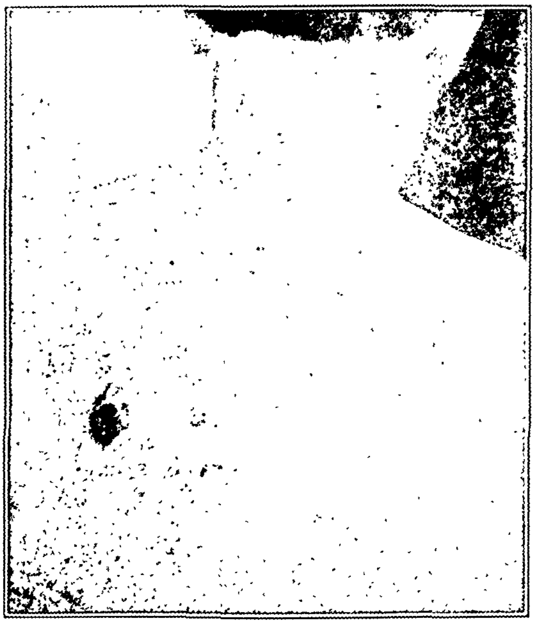

Fig. 1.—Primary carcinoma of back with metastases in axilla and neck (Case 5).

Many times it seems to me cruel to allow such a patient to linger toward a certain death and stand by while he is dying by inches. In the course of the last few years, however, I have been able to snatch a few cases from such certain death, and since years have elapsed from the time of treatment and no recurrence has taken place, I feel that there is a *possibility of doing* some good in some of such cases by a more extensive operation, It consists in the exarticulation of the whole shoulder-girdle, including clavicula, arm and scapula, with the plexus and the vessels of the affected side, with the ribs, if necessary, should they seem invaded by the carcinoma. It may be that such procedure has been done elsewhere; I have not taken the trouble to go through the literature to find instances of that kind; at any rate the procedure is not common and its publication may be useful to recommend it.

The technic of the operation is not simple in every case, and there cannot be prescribed a definite plan in detail. In the individual case there must be an individual plan in order to make the operation safe. It is a very extensive operation and requires great delicacy, because of the removal of such a large part of the body. The section of such large nerve trunks is a great shock to a person afflicted for a long time and often not in the best condition.

On the whole, however, it begins with the formation of a large skin flap destined to cover the whole area of the defect, the exarticulation of the clavicle following, then dissection of the tissues of the neck and axilla in one block, ligation of every vessel as it is reached, cautious cutting of one nerve after the other, and lastly, the separation and excision of the scapula. Altogether I have done this operation eight times in nine years. All cases were desperate, some of the patients operated on several times by myself or others, were all considered inoperable, some of them having consulted the best operators of the country, who declared surgical operations useless.

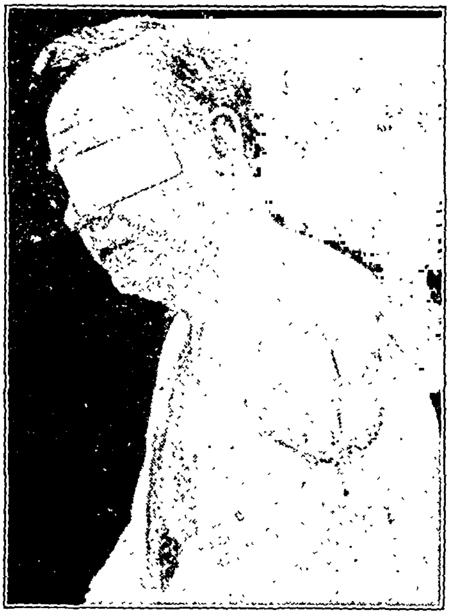

Fig. 2.—Patient (Case 5) five years after last operation.

REPORT OF CASES

Case 1.—Mrs. M., aged 34, had carcinoma of the breast. Radical operation in 1905. One year after operation recurrence in supraclavicular region, glands in axilla, swelling of arm, severe neuralgia; several secondary incomplete operations afforded no relief. There were strabismus, with rigid contraction of neck, a regular torticollis from contracture, and severe headaches, showing diffuse dissemination. I decided to remove the shoulder with adjoining glands and all tissues of the neck (1906). The patient was relieved and lived about six months but finally died from intracranial carcinomatosis.

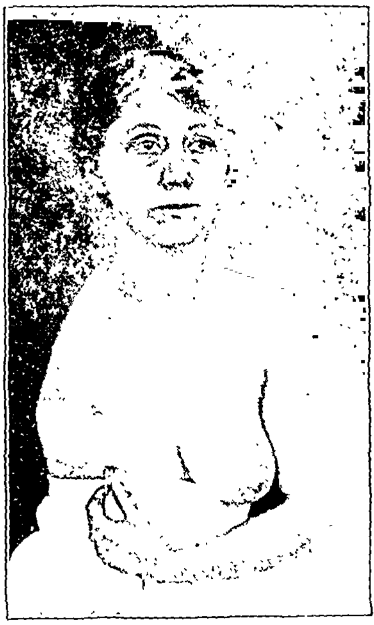

Fig. 3.—Patient in Case 6 shortly after removal of shoulder girdle.

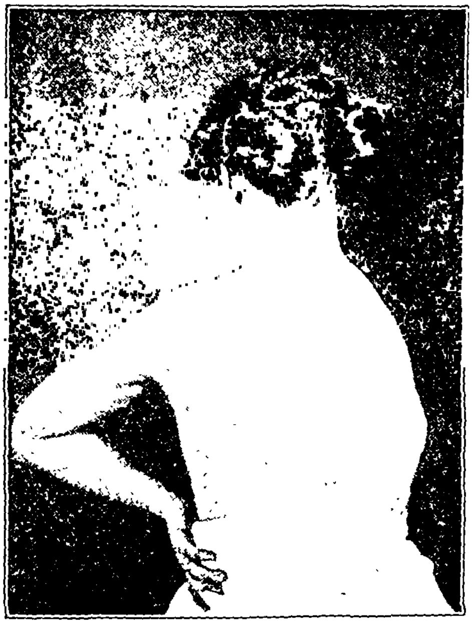

Fig. 4.—Patient in Case 6, posterior view.

Case 2.—Mrs. C., aged 60 years, an old Italian woman. History similar to that of Patient 1. Operation was performed in 1907 for carcinoma of the breast; several incomplete secondary operations by different surgeons. In 1908 the patient was suffering from intolerable pains in arm and chest, a tumor pressing on the plexus, and coughing spells; arm immovably adherent by carcinoma to the chest; a desperate case. In September, 1908, she was operated on by exarticulation of the shoulder-girdle. The upper four ribs, closely connected with the carcinoma, were resected with the tumor. The patient made a good recovery, and lived three years practically free from symptoms. I have not heard from her since 1911, and have not been able to locate her. Most probably she has died since that time.

Case 3.—Mrs. Z., aged 65, a German housewife, with carcinoma of the breast, was operated on several years ago in Germany; had in 1909 a recurrence deep under the axilla, with immovability of the arm, which was edematous and painful. The case was very favorable for radical operation with exarticulation, which was done. The patient made a good recovery, but developed erysipelas after the operation and had to be removed from the hospital. She died of erysipelas at her home.

Case 4.—Mrs. C., Italian, aged 58. A case similar to Case 1. Exarticulation performed in 1909 with good surgical result, but had a complication showing that the pleura had been invaded. The patient lingered for some time and then died.

Case 5.—Mr. J. F., recommended to me by Dr. H. on account of carcinoma of his back (Fig. 1). Radical operation was performed, with excision of the infected axillary glands. Free for some time; then there was a recurrence of the tumor on the neck above the clavicle and extending into the middle of the neck. Extirpation of the cervical glands in a secondary operation. Relatively well for several months, but returned with recurrence in the axillary pit, with a large group of indurated glands, swelling of arm and pain. Removal of these glands afforded no relief; patient developed lymphangitis of arm and severe septic infection, which ran him down considerably. After he had recovered from this operation the patient felt somewhat better than before, and attended to his business, though not free from recurrence, which showed on the neck again. The arm was only partly movable and swollen. At this time I proposed exarticulation as a last resort. The gentleman, who holds a prominent position, could not decide to have it done and consulted different surgeons. One of the most prominent wrote: "I cannot see how anything can be done except treatment with Coley's serum or morphin."

Seeing no alternative, the patient finally submitted. The operation was performed in the presence of a prominent surgeon of London, England, who happened to be visiting me at that time. The patient made an absolute recovery and has been free from recurrence since, now five years (Fig. 2).

Case 6.—Miss J., school teacher, aged 30, was brought to my office from the depot, just about to return home from the hospital. She had a severe hemorrhage from a tumor of the breast. All the patient's clothes were saturated with blood, which was running down on her body. She had been at one of the hospitals for several weeks, treated with the Roentgen ray for an inoperable carcinoma of the upper breast and was sent home with the decision that nothing more could be done. Before her entrance to the hospital she had been operated on at home twice within a year by her local physician, an incomplete removal of the breast tumor having been done; then she came to Chicago, but radical operation was thought impossible by one of our most competent surgeons. As she reached the depot the hemorrhage occurred. Hemorrhage had occurred twice before while at the hospital. By a compression bandage I stopped the hemorrhage and after two days we took a roentgenogram, ascertaining that the pleura and lung were free. I decided on exarticulation. Technic as usual. She made a quick and splendid recovery and has been well since; has had no recurrence and was shown at the Clinical Congress of Surgeons in 1913 (Figs. 3 and 4).

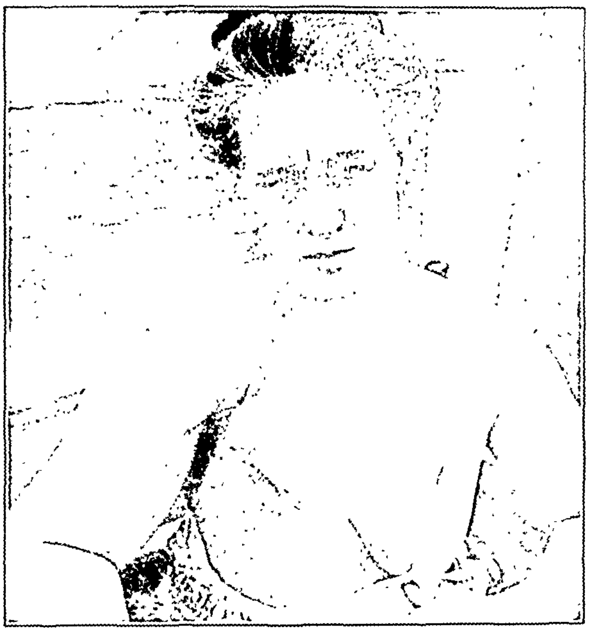

Fig 5.—Patient in Case 7, showing condition after several radical operations. Note neck and both arms.

Case 7.—Mrs. A., aged 54, came to me after having been operated and reoperated on twice for carcinoma of the breast. Had all the typical symptoms of secondary carcinoma of the type described above. Her appearance seemed to indicate that she would make an excellent case for our operation. The only difficulty was the very tight scar formation around the neck of the humerus, owing to the different dissections (Fig. 5). In this case I learned that we have to be careful in sectioning the nerve trunks, and particularly the deep nerves of the neck, vagus and phrenicus. I cut several large nerves and at once pallor and weak pulse appeared and deep shock followed, from which the patient rallied slightly only for a time. Just as I completed the dissection she died.

Case 8.—A few weeks ago I operated on Mrs. S., a poor woman, who suffered agonizing pain from a recurrent tumor of the breast and neck after a radical operation. She was in continuous pain and morphin would not stop it. I decided to cut the nerves of the plexus only, as it seemed impossible to remove the carcinoma even with such an extensive operation as exarticulation. On the fourth rib, near the sternum, was an isolated, ulcerated tumor which could not easily be removed (Fig. 6). Under novocain I dissected out and cut one nerve after the other of the plexus.

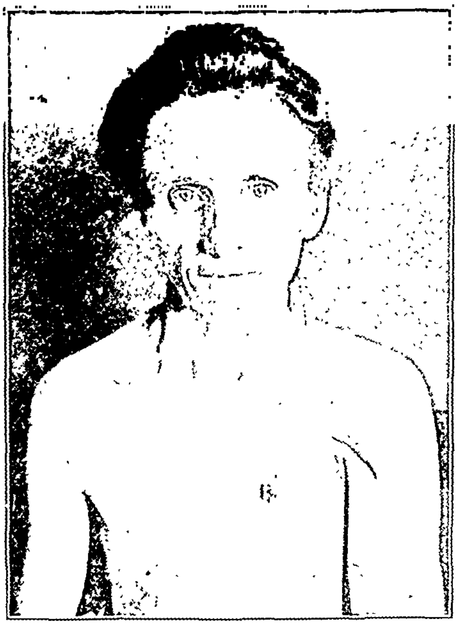

Fig. 6.—Patient in Case 8, showing difference in the arms, solitary carcinoma on chest and metastasis in left side of neck.

Following the operation, the actual pains in the arm stopped, but on the neck and around the shoulder there was still neuralgia. The arm was so heavy that the patient said it felt like a ton and therefore I removed it at a second operation, and since that time the patient is free from pain and has also improved in general health. The isolated recurrence of carcinoma on the ribs is yielding slowly to the blue rays. The Roentgen ray seemed to make it disappear more rapidly, but patient seemed to grow weaker, it was thought, on account of too rapid absorption of the destroyed carcinoma material.

Summing up these results, I may say that while they are not ideal, considering the desperate condition of the cases, they are very good and the procedure seems to me commendable. After all, when I look back on my results in twenty-six years of surgical practice, the only permanent relief I have ever seen from any remedy in carcinoma was from the knife, and all other agencies on which I have pinned a great deal of hope at first, have in most instances disappointed me. Most important of all seems to me the deduction that even some of these apparently hopeless cases have still a slight chance when we go to the limit.

108 North State Street.

The Mortality Bill Against Alcohol.—In a number of life insurance companies, chiefly in Great Britain, the abstainers were separated from the rest of the policy holders (all accepted as temperate and healthy risks), and the difference in the death rate determined. In one institution of London over a period of forty-five years the mortality of the nonabstainers, or so-called moderate drinkers, accepted as temperate and healthy risks, was 37 per cent. higher than that among the total abstainers. In another association of London over a period of twenty-seven years the mortality of the nonabstainers was 54 per cent. higher than among the total abstainers. In a third life assurance company of Glasgow, over a period of twenty-nine years, the mortality of the nonabstainers was 44 per cent. higher than the mortality among abstainers. In a Canada company over a period of eight years the mortality of the nonabstainers who had been accepted as temperate and healthy risks was 78 per cent. higher than among the abstainers.—Monthly Health Letter, Life Extension Institute.

FRACTURE OF THE PATELLA

AN ORIGINAL METHOD OF RETAINING THE FRAGMENTS IN APPOSITION

JOHN A. WYETH, M.D., LL.D.
Surgeon-in-Chief to the New York Polyclinic Medical School and Hospital
NEW YORK

For the last three years, the following simple and successful method has been employed in recent cases of ordinary transverse fracture of the knee-pan:

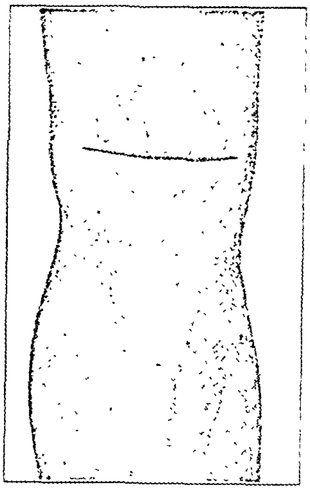

Fig. 1.—Line of incision across the middle line of the sulcus due to separation of the fragments.

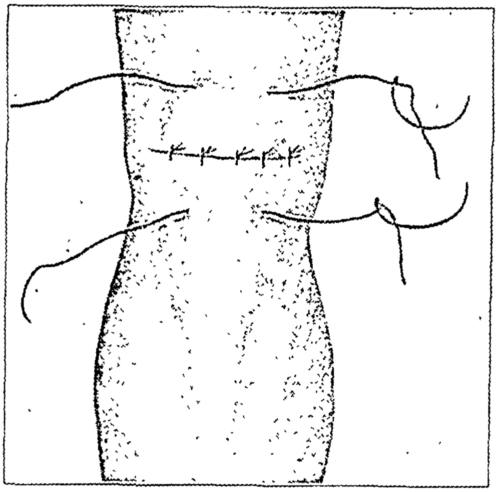

Fig. 2.—The retaining sutures of linen inserted and the incision closed, after removing the clot and reuniting the torn edges of periosteum.

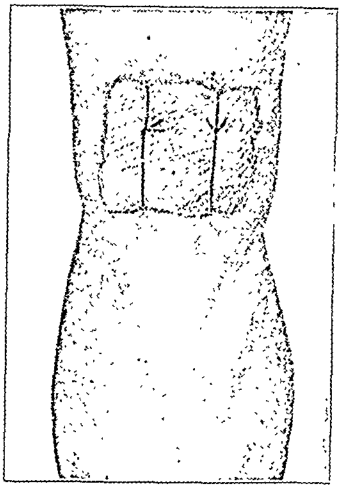

Fig. 3.—The dressing applied and the retaining stitches tied.

The edges of the fragments are exposed by a transverse incision over the center of separation, and the intervening clot washed out with reasonably hot salt solution, a syringe being used with as much force as is necessary to cleanse thoroughly. A gentle swabbing would suffice, but water gives a minimum of traumatism.

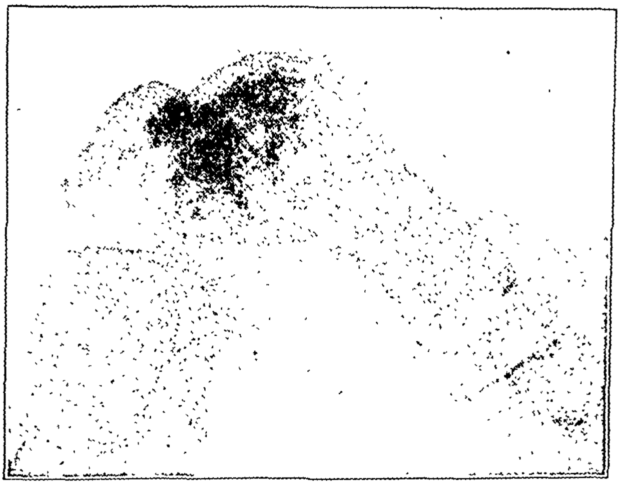

Fig. 4.—Roentgenogram one year after operation. Extreme flexion; function normal.

The opposing frazzled edges of overhanging connective tissue are now carefully stitched with a continuous, very fine linen suture, and the skin incision closed with running chromicized gut.

The holding device is as follows:

A strong quarter curved needle (Hagedorn by preference) threaded with extra large linen (No. 5) is carried across the lower border of the lower fragment, dipping greedily into the substance of the ligamentum patellae, just along its expanded attachment to the patella.

The points of entrance and exit of this needle should be about 1¼ inches apart, and the thread ends left 8 inches long.

The same maneuver is practiced along the upper edge of the upper fragment, the needle going well into the quadriceps extensor insertion, but not entering the bursa beneath this tendinous expansion.

Two strips of sterile gauze are now laid over the incision, and over these are tied very firmly, as one would tie one's shoestrings, the upper and lower ends of the opposing threads. In this way, not only are the fragments held in perfect contact, as no separation by muscular contraction is now possible, but also they cannot be tilted, or override.

A plaster-of-Paris cast is applied over all, from the ankle to near the groin, and the patient kept in bed for a week, with the foot elevated on a pillowed chair. After this, locomotion on crutches is permitted *ad libitum*. The dressing is not disturbed for six weeks, when the threads are removed, and then slight passive motion is made, while the fragments are very strongly supported. The cast is readjusted, and there is a repetition of this two weeks later, and again, two weeks further on. The knee should be guarded from overstrain for at least six months, as a common-sense precaution. The danger of ankylosis is nil.

I have always done this operation with ether anesthesia. If done with novocain, the holding threads should first be inserted, as an assurance against possible involuntary contraction of the quadriceps extensor.

Figure 4 shows the result one year after operation. The function is perfect.

244 Lexington Avenue.

Industrial Accidents.—A conservative estimate of the economic loss in this country through industrial accidents places it above a quarter of a billion dollars each year. This is more than two million workmen could earn in twelve months at $4 a day.—*From an address by J. Kirby, Jr.*

New Instruments and Suggestions

A NEW BONE CLAMP

R. E. Farr, M D., Minneapolis

This instrument is designed for the purpose of reducing and holding reduced the fragments of a fractured bone, when the open treatment is indicated, while one of the various forms of fixation methods is applied.

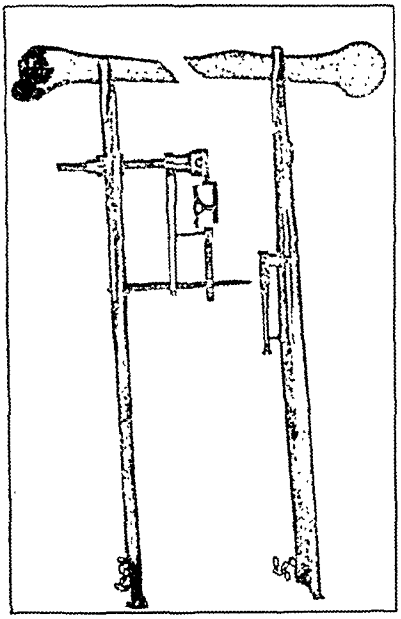

Fig. 1.—Farr bone clamps in position for reduction of fracture.

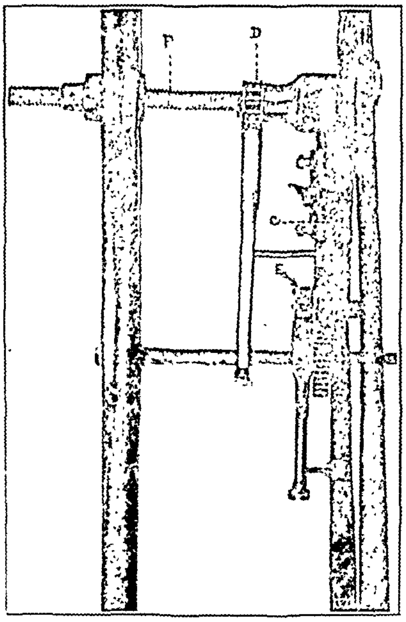

Fig. 2.—Mechanism of clamp. *C*, clasp for locking forceps together; *D*, ratchet by means of which shortening is overcome; *E*, ratchet for lateral movement of fragments; *F*, bar as fulcrum.

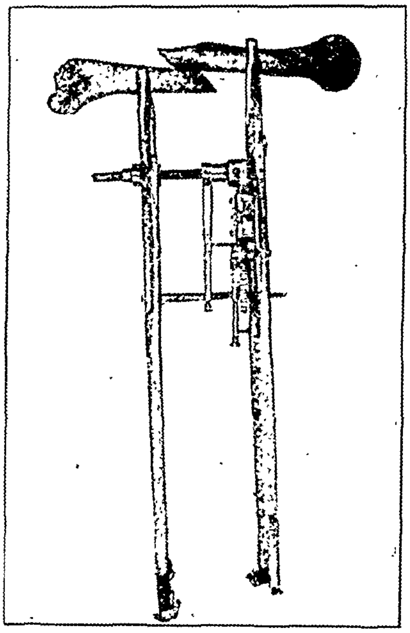

Fig. 3.—Clamp in position for reduction of overriding.

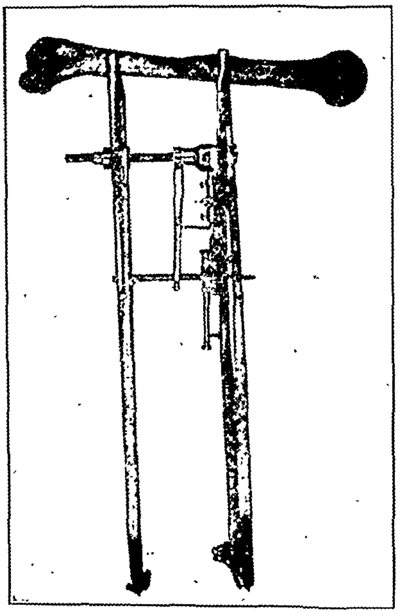

Fig. 4.—Ends of fragments in apposition.

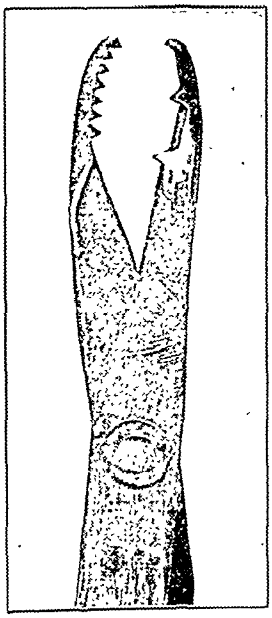

Fig. 5.—Grasping surface of forceps.

It consists of two pairs of long-handled forceps (Fig. 1), with two ratchets which work in planes at right angles to each other. The technic of application is the following:

After the point of fracture is freed, one clamp is placed on each fragment at right angles to its long axis and at points which will allow the forceps to be locked together with the clasp *C* (Fig. 2). The only other requirement before locking the forceps together is that the fragments be held parallel to each other or nearly so. Providing there is overriding, which is usually the case, the ratchet at *D* (Fig. 2), is worked to and fro until the shortening is overcome. Here I have made use of the jack-screw described by Gerster but have added the ratchet attachment which I find to be a decided improvement. This ratchet is reversible and after the fragments are moved laterally by the use of the ratchet *E* (Fig. 2), and brought into alignment, they may be made to engage with all of the precision one may desire (Figs. 3 and 4). An alternate upward and downward movement of the handles with the bar *F* (Fig. 2), as a fulcrum in addition to the movements given by the ratchets *D* and *E* gives one absolutely complete control over the fragments. In applying the fixation of Lane, a clamp may be used temporarily at the line of fracture, once the reduction is accomplished, and the other clamps may be released sufficiently to allow the metal splint to be slipped into place, when it is securely held by a second closure of the clamps while the screws are inserted. This first model, though crude, seems to fulfill the indications for which it was designed. Figure 5 shows the grasping surfaces of the forceps. They are designed to hold the bone securely, both before and after the Lane plate is in place. The distance of the ratchets from the field of operation renders the carrying out of an aseptic technic easy and certain. The handles are made long and flexible and are locked with chains. They will hold securely a bone of any size.

Suite 301, Reid Corner.

Density of Population and Infant Death Rate.—Based on the school census for 1914 it was found that the average number of people per in Chicago is 19.5. The wards having death rates above the average have an average of 49.7 people to the acre. It is not congestion alone, but congestion plus bad sanitary conditions that produce high infant death rate.

TUBES FOR INTRA-URETHRAL MEDICATION

MAX GOLDMAN, M.D., KANSAS CITY, MO.

For the introduction of various medicinal substances into the urethra I have devised, and have been employing for some time, a series of tubes modeled after the pattern of the Ultzmann instillation syringe. These tubes are made of sterling silver, and range in size from 14 F. to 24 F. In shape they follow the curve of the classical urethral sound, and all have capped ends with threads suitable for the attachment of the universal hypodermic syringe. By means of adaptors they can readily be adjusted to fit all glass and record syringes.

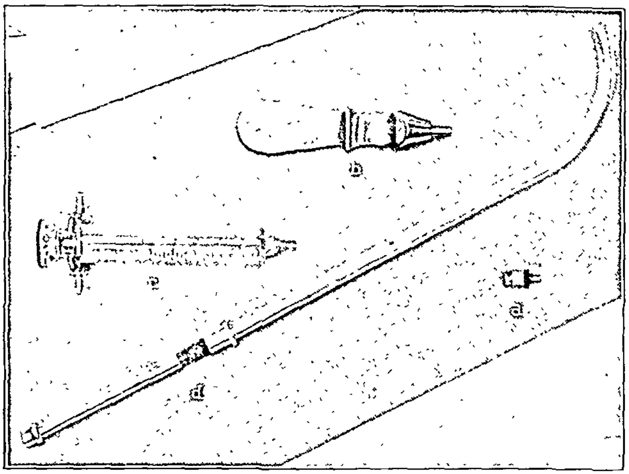

Fig. 1.—Urethral tube and accessories: (*a*) adaptor, (*b*) sound handle, (*c*) syringe, (*d*) irrigating nozzle.

There is also a sound handle, which is likewise adjustable, so that each tube can easily be converted into a urethral sound. In addition, another attachment is supplied in the way of a short silver tube, much like the ordinary glass irrigating nozzle, but having an adjustable small end for attachment to the tubes, to be used in cases in which irrigation of the bladder or urethra is desired.

The value of these tubes is enhanced by the fact that (1) they can be used (*a*) as sounds in any stage of the disease (for instance, urethritis); (*b*) not only as a means of instilling medicines in the posterior urethra, but also for placing any variable amount of an agent anywhere along the urethral canal from the vesical orifice clear out to the urethral meatus; (2) any size can be used, thereby avoiding irritation of the mucous membrane; (3) irrigation can be gently made with any one of the instruments, and followed by the injection of some medicinal agent without too much instrumentation; (4) the effect of both sound and tube is secured without the additional use of a sound proper.

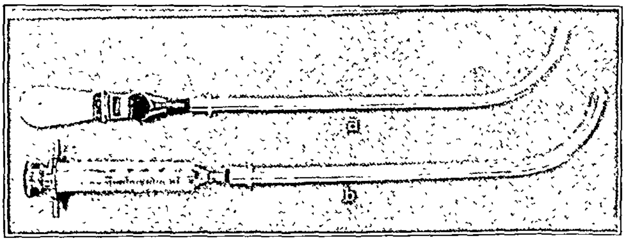

Fig. 2.—Urethral tube, converted into (*a*) sound, (*b*) syringe.

In chronic posterior urethritis or gleet this treatment will be found of the highest value; and in urethral stricture of long standing it is of much assistance when combined with other methods in softening up inflammatory indurations, and relieving congestion of the mucous membrane. After cystoscopic examinations or urethral examinations in which considerable instrumentation has been carried out, a local treatment with one of the tubes, an albuminate of silver preparation being placed along the canal from the bladder outward, will do much in the way of preventing a urethral chill or infection by its antiseptic and astringent effects on the mucous membrane.

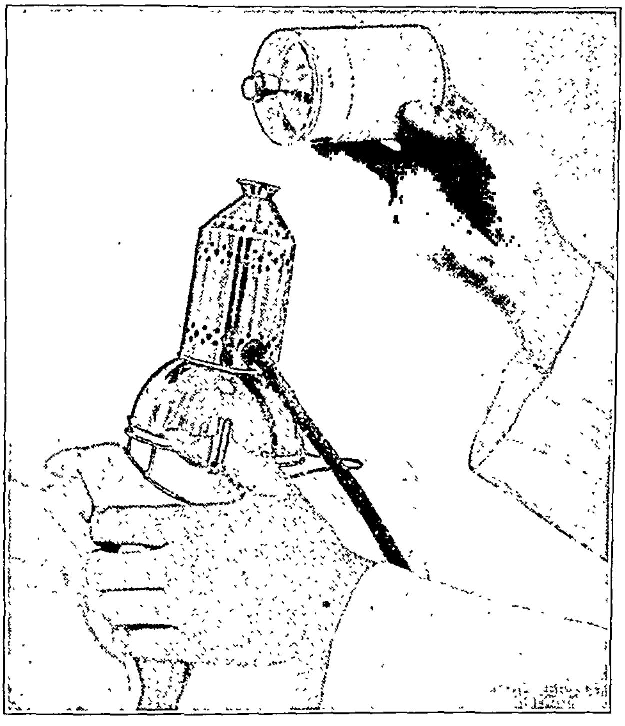
If undue difficulty is experienced in introducing the instrument, sterile glycerin may be used as a lubricant, but as a rule the medicinal agent itself is sufficient for this purpose.

1222-1223 Rialto Building.

A NEW METHOD FOR ETHER ADMINISTRATION

J. W. SNYDER, M.D., MICHIGAN CITY, IND.

I have endeavored to devise a simple means of securing a positive warm ether for anesthesia, a method which would employ the principles of the open mask and would have the added feature of a warm anesthetic. To do this I have employed the ordinary mask and have superimposed on it an electric heating coil. This coil is built about a seamless brass tube placed vertically to the top of the mask. The tube at various levels has wire gauze screens and plates which become heated from the surrounding coil, and which in turn heat the ether as it is passing through them. The coil is attached to the mask by means of a casing which extends part way down over the mask proper. The coil and casing may be quickly detached from the mask by a slight turn to the right, leaving the mask free. The coil is built for the usual 110 volt alternating city current, and is so constructed that it has a maximum temperature and will not become too hot if connected up for an indefinite time. In use the coil is attached to the city circuit and left on for about twenty minutes before the anesthetic is started. As previously indicated, the coil needs no regulating, as it will not become hot enough to decompose ether if left in circuit for hours, and it is only necessary to keep it connected to use it repeatedly.



Apparatus in use, showing thumb of left hand holding mask in position while the fingers support the jaw. The heavily insulated cord for connection to the city current is shown and also the manner in which ether is dropped through the coil.

The mask portion proper is prepared with layers of gauze as is usually done, and when the coil has been connected for a period of twenty minutes as previously described, it is attached to the mask, and both are placed over the patient's face. From this time on the anesthesia is by the ordinary drop method, except that instead of dropping ether on the mask, it is dropped through the brass tube inside the coil, and so reaches the mask proper as a warm gas. The only caution at this period is to give the ether more slowly and in smaller amounts than by the cold method, as it reaches the patient more quickly and more is available to the patient after being heated than when it is dropped cold on the mask. Towels may be placed about the mask as desired, but in the majority of cases they are not required, and in practically all they may be removed as soon as full narcosis is reached. In this way we give an abundance of air to the patient and as a result have little cyanosis. The patient's good color throughout has been quite remarkable. During the period the anesthetic is being crowded, a little of the ether may reach the gauze of the mask unchanged; but the coil will speedily regain its temperature as soon as the rate of administration can be somewhat slackened, and will again convert all of the ether to a gas. As the patient breathes, warm air is inhaled and exhaled, as can be readily noted, a quite different matter from breathing through a mask covered with ice crystals of the exhaled breath.

As to the results in the employment of this method, I have observed the following:

1. The patient goes to sleep more easily without coughing or holding his breath.
2. There is an absence of second stage excitement in the great majority of cases.
3. It is a dry anesthesia, with absence of mucus from the air passages, except in the deepest prolonged anesthesia.
4. Anesthesia is easily maintained.
5. As a rule, the patient is brighter on awakening and awakens in a shorter time.
6. Postoperative nausea and vomiting are absent.
7. By reason of conserved bodily heat we should expect shock to be less; and this conservation, together with absence of bronchial irritation, tends to lessen the occurrence of postoperative ether pneumonia and bronchitis.
8. The total amount of ether used is diminished by approximately one-half.

AN ACTUAL POCKET MERCURIAL SPHYGMOMANOMETER

Hugh Hamilton, M.D., Harrisburg, Pa.

I have found the various sorts of blood pressure instruments defective in one essential—all are bulky. Of the two kinds of mercurial and dial gages, the mercurial is esteemed the best. In an effort to devise an instrument which could be carried on the person without exciting curiosity in private practice, the one illustrated resulted.

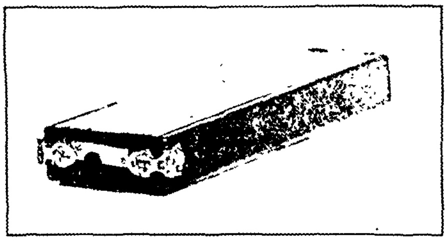


Fig. 1.—Pocket mercurial sphygmomanometer closed.

The mercurial hinge cock for the mercury is from an instrument made by Tagliabue. I claim only reduction in bulk and consequent mechanical arrangements, the whole apparatus weighing about 1 pound.

The photographs are precisely at the identical focus. Therefore the comparative size open and shut is represented in true proportion.

After careful comparison the mercurial column may be regarded as the most certain to give true results because it is fixed at a zero by gravity and not through artificial standards essential in all other devices dominated by springs as dial instruments, that may some time or other lose the zero, which automatic quicksilver will not do. In this little box I have added beside the U tube a thermometer for the room temperature. At the time of taking an observation of a "pressure" the body temperature is also then noted; across the space in the U tube about midway a level is inserted in the wooden support.

The wooden support for the U manometer of the sphygmomanometer is a free lid to the box. The edge under the curve of the U fits upright into a slot in the center of the box, fastened by braces rising from opposite ends of the box. On the bottom of the box are four blades that extend at right angles to the length of the box resembling when opened "a turtle." This little box is 8½ inches long, 2¾ inches wide and 1¾ inches thick or 22 by 7 by 3 cm. The hope is that this small (actual pocket) case may make the employment of the accurate mercurial sphygmomanometer available in clinical private practice and assist all in more precise prognoses.

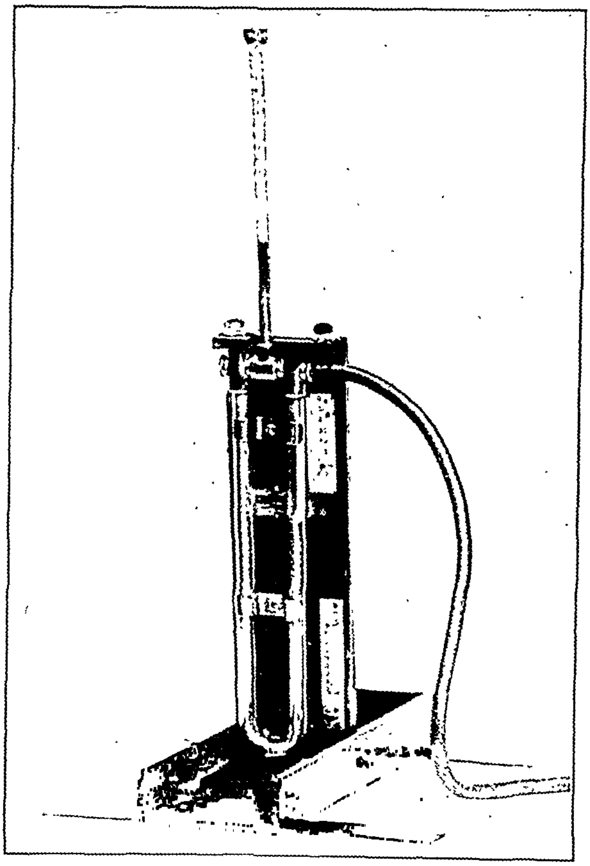

Fig. 2.—Pocket mercurial sphygmomanometer open for use.

ADJUSTABLE SPLINT FOR FRACTURES ABOUT THE ELBOW JOINT—CONVENIENT STAND FOR THE DIAGNOSIS OF PES PLANUS*

Willis E. Hartshorn, M.D., New Haven, Conn.

ADJUSTABLE SPLINT FOR FRACTURES ABOUT THE ELBOW JOINT

Fractures of the external and internal condyles of the humerus, T-fractures into the elbow joint and comminuted fractures in this region often afford occasions in which an adjustable angular splint can be used to great advantage. The splint, a description of which is here outlined, is distinctly a simple affair which can be made by any one in a comparatively short time. This fact offers the chief reason for its presentation. It consists of two wooden splints *A* and *B* (Fig. 1), the length varying in children and adults. These are connected by an ordinary door hinge, *C*. This is held in position by small stove bolts and nuts. The pin which ordinarily connects the two parts of the hinge is driven out. The inner edge of one side of the loop and the outer edge of the corresponding loop in each case is tongued and grooved with a file as noted in the sketch. A thumb bolt and nut is substituted for the original pin, and the splint is complete.

---

* From the Surgical Service of the New Haven Dispensary.

The general utility is emphasized because it can be tightly folded together and placed in a bag. The two wooden parts can be removed by unscrewing the nuts on the heads of the bolts, and they can together or separately be used in fractures of the forearm, hands or fingers. Any degree of angle from the most acute can be formed in a moment's time without the removal of the splint from the extremity. A fracture of the olecranon can be treated in the extended position or in the semiflexed position. In fractures occurring in the upper third of the forearm where it is necessary to immobilize the elbow joint, it will be found useful, an anterior wooden splint supplementing the posterior. To tighten the splint so that it will hold firmly the angle needed, the thumb bolt is set with a wrench. With the ordinary commercial hinge, the loops at the center are a little too thick to admit of adjustment with the fingers alone. If desired, these loops can be filed thinner so that the thumb can be used to fix the angle; this, however, requires either a specially built hinge or the expenditure of a little more time in the making. Figures 2 and 3 show the application of the splint.

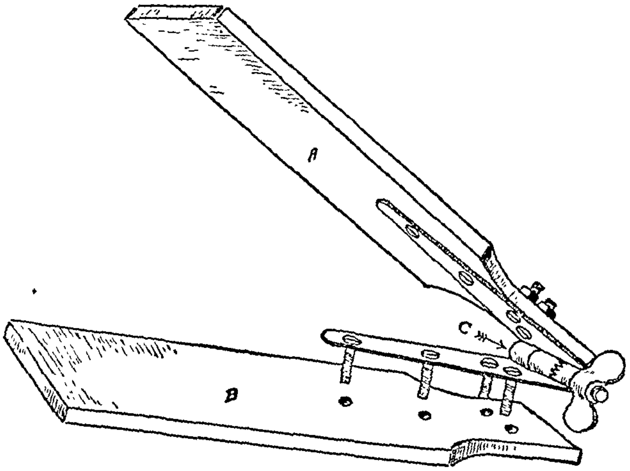

Fig. 1.—Adjustable splint.

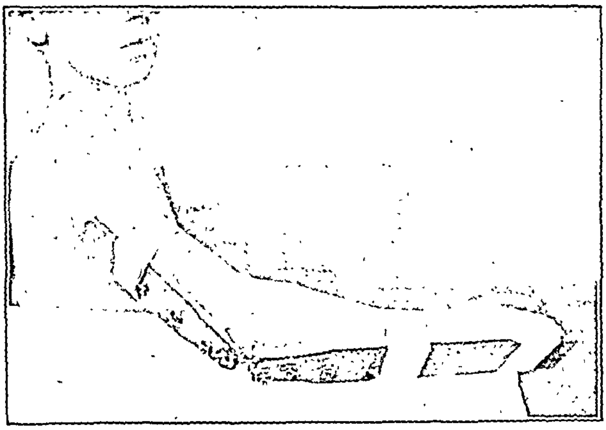

Fig. 2.—Adjustable splint applied to extended forearm.

CONVENIENT STAND FOR THE DIAGNOSIS OF PES PLANUS

At the suggestion of Dr. Joseph M. Flint of the department of surgery, who had observed in one of the European clinics visited by him a similar stand, the one illustrated was constructed at the surgical laboratory and has been found useful in the surgical clinic of the New Haven Dispensary as an adjunct to the general physical examination of patients. It deserves consideration because it presents a simple method of determining the condition of the arches when symptoms including pain in the legs and feet are presented.

In the illustration (Fig. 4) it will be noticed that the area of pressure on the sole of the foot is sharply contrasted with the normal tint of that portion free from pressure. In actual use this is much better shown. If the pressure area encroaches on the inner side of the foot, the various grades of pes planus are suggested. This simple apparatus does away with the need of the patient's standing on blackened or wet paper, is always ready for service, and gives instant indication of pressure wrongly directed or a weakened arch.

Fig. 3.—Adjustable splint applied to flexed forearm.

It consists of a box made of white wood, two sides of which are omitted. The mirror is inserted obliquely on the inside at an angle of 45 degrees. The top of the box should be of heavy plate glass at least half an inch in thickness. This thickness should be emphasized, as otherwise there might be danger of its breaking under the weight of the patient, and a serious accident occur.

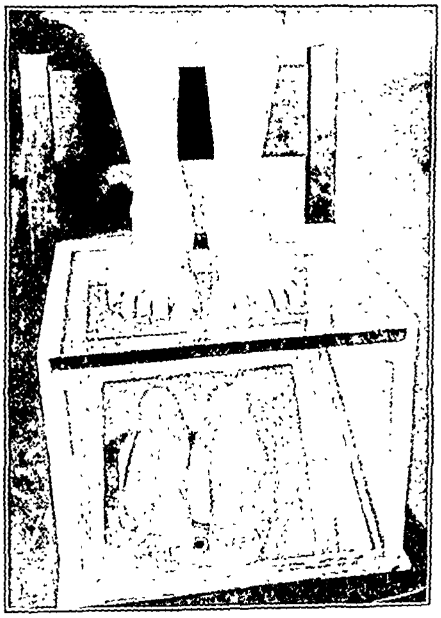

Fig. 4.—Stand for pes planus.

This simple stand is of course not of especial assistance in actual orthopedic work; but in the ordinary routine of a surgical clinic, it saves time and has proved an effective and valuable assistant in the diagnosis of arch conditions which are of such frequent occurrence in the type of patients frequenting a dispensary.

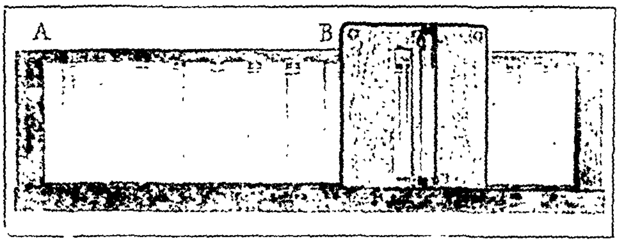
1138 Chapel Street.

A SIMPLE COLORIMETER FOR USE IN THE PHENOLSULPHONEPHTHALEIN TEST FOR KIDNEY FUNCTION

James S. Brotherhood, M.D., Grand Rapids, Mich.

The use of the phenolsulphonephthalein test of Rowntree and Geraghty[1] for estimating renal function has became quite widespread and were it not for the expense of the instruments for determining the percentage of phenolsulphonephthalein the test would enjoy even greater popularity.

The several instruments at present on the market (Duboscq, Autenrieth-Königsberger and Dunning colorimeters) are all reliable, but too expensive for the average practitioner. Acting on the suggestion of Drs. Cabot and Young[2] I have devised an instrument which is of simple construction and can be made at small expense. It has proved reliable and will give readings within 2 per cent., when compared with the Geraghty-Rowntree modification of the Autenrieth-Königsberger colorimeter, also when compared with known and measured dilutions of the standard solution.



Colorimeter for Use in Phenolsulphonephthalein Test for Kidney Function; *A*, wooden rack to hold test-tubes filled with dilutions of a standard solution of phenolsulphonephthalein; *B*, movable shield holding test tube whose phenolsulphonephthalein content is to be determined.

The instrument consists of a wooden rack to hold 14 small test-tubes (12 x 120 mm., the size used for the Wassermann reaction). Fitting over the rack and sliding in a groove in base of rack is an upright shield-piece which has two oblong apertures to permit the passage of light through the test-tube in the rack, and a second test-tube which is held in the shield and which contains the specimen whose phenolsulphonephthalein content is to be tested. The remainder of the shield, on either side, protects the observer from side light interfering with accurate matching of the colors in the test-tubes. The test-tubes in the rack are filled with varying percentages of the phthalein, from 5 to 70 per cent. The dilution is made from a standard solution of 6 mg. of phenolsulphonephthalein to one liter of distilled water, to which is added sufficient sodium hydrate (10 c.c. of 5 per cent. solution or a few cubic centimeters of concentrated solution) to bring out the color of the dye and to render the solution more permanent. It has been found of advantage to use chemically pure rubber corks and paraffin in sealing the tubes, as ordinary corks tend to discolor the solution. With ordinary care, and preventing the color tubes from being exposed to direct sunlight for long periods, there will be little if any fading of the color and this simple apparatus will give excellent service.

The method of estimating the quantity of phenolsulphonephthalein excreted, using this colorimeter, is the following: Dilute the specimen of urine to about 200 c.c. with water, and render alkaline by adding 10 c.c. of 5 per cent. solution of sodium hydroxid and the further addition of water to make it measure 1 liter. With this dilution fill a test-tube the same size as used in the rack and place in front of aperture in shield; then by moving shield along the rack to a point where a color tube in the rack most nearly matches the specimen, the percentage of this color tube will correspond to that of the specimen tube and represent the percentage of the dye (phenolsulphonephthalein) secreted.

Occasionally it is found that after adding the sodium hydroxid to the specimen the coloration is slight; the dilution should then be made to 500 c.c. instead of 1,000 and the percentage reading divided by 2. Directions for application of test and phenolsulphonephthalein in sterile ampoules (containing 6 mg. to 1 c.c.) may be obtained from Hynson, Westcott and Company, Baltimore.

Grand Rapids Clinical Laboratory.

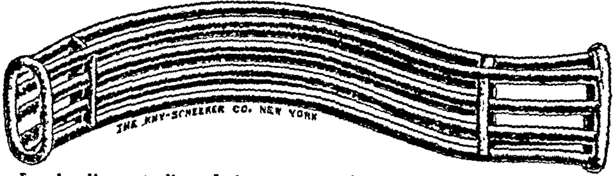
A CONTROLLER OF THE TONGUE AND PALATE DURING GENERAL ANESTHESIA*

Joseph E. Lumbard, M.D., New York
Instructor in Anesthesia, University and Bellevue Hospital Medical College; Anesthetist to Harlem, Knickerbocker and Lying-in Hospitals

It is of great importance to maintain an unobstructed air way during the administration of a general anesthetic. The prevention of obstruction to free breathing through the upper air passages is one of the most important details with which the anesthetist has to cope. The most common form of respiratory obstruction, during anesthesia, is the falling back of the tongue into the pharynx, owing to the relaxation of the muscular support.

There are several instruments to overcome this difficulty, known as air ways, breathing and pharyngeal tubes. Those best known are the tubes devised by Hewitt of London and Connell of New York. Both give excellent results, but are open to the great objection of becoming obstructed with mucus.

To overcome this I have devised an instrument which consists essentially of a double row of four bent wires, running parallel, about an eighth of an inch apart, and firmly held together by wire bands, two at each end. The instrument measures 5½ inches in length, three-fourths inch in width and one-fourth inch in thickness: It presents a double curve which adapts itself to the dorsum of the tongue. The instrument is easily introduced, by placing the pharyngeal end between the tongue and the soft palate, until it rests in the pharynx. No attempt should be made to do this until the patient is well anesthetized. The use of the instrument is also indicated in obstructions of the nose and mouth. It obviates the barbarous methods of tongue retraction and jaw holding, and an instrument of this nature should be considered as an essential part of every anesthetist's outfit.



Lumbard's controller of the tongue and palate for general anesthesia, thirteen-twentieths actual size. The pharyngeal end is at the left.

ADVANTAGES

1. It is easily and quickly introduced. No mouth-gag or manipulating of the tongue are necessary.
2. It will not clog with mucus, which is the chief defect of similar instruments.
3. It is easily kept in position.
4. It is quickly cleansed.
5. It will not conduct a fluid anesthetic to the throat, an accident that is liable to occur with other instruments.
6. It cannot be compressed by the teeth or gums.

CIRCULATORY DEPRESSANTS

It is well known that, though the blood-pressure undergoes frequent minor changes, it is under the control of a coordinated mechanism which tends to maintain a close approximation to a certain level from day to day during health. Even after the administration of drugs which affect the distribution of the blood, any considerable change in blood-pressure is usually only fleeting. When the vessels of the splanchnic region are constricted, those of the periphery usually undergo a compensating dilatation; if the constriction of the splanchnic vessels is sufficient to cause a rise of blood-pressure, the heart is commonly slowed, so that the pressure in the large arteries tends strongly to remain constant.

The blood-pressure may be lowered by diminishing the amount of blood in the circulation; by dilating the vessels, or by diminishing the activity of the heart by decreasing either its force or its rate.

Venesection, or bleeding, was formerly employed widely, but this has fortunately fallen largely into disuse. Drastic cathartics were also used at one time somewhat more freely than at present; diaphoretics and diuretics remove liquid too slowly to be satisfactory in those emergencies in which vasodilators are commonly used. The blood tends strongly to maintain a uniform concentration, and when much fluid is removed by diuretics or diaphoretics this is largely replaced in the circulating blood by fluid drawn from the tissues.

There is an even greater tendency on the part of the vasomotor mechanism to compensate for changes induced in the vessels of different areas, and the vasodilators often exert only an inconspicuous and brief influence on the general blood-pressure.

The rate of the heart-beat is influenced by many factors which tend to regulate it according to the demands of the circulation. Consequently, the heart often responds to the systemic actions of drugs in a manner directly opposite to that which would result from the action on the heart alone.

Vasodilators: The Nitrites

Therapeutic doses of many drugs cause dilatation of the vessels of certain areas, and many cause general vasodilatation when toxic doses are given.

Attention has been called to the dilator action of the antipyretics on the vessels of the skin whereby they promote sweating and the elimination of heat. They are not used to lower the general blood-pressure, however, even though this does result from their collapse action.

Alcohol also causes dilatation of the peripheral vessels even with small doses, and it was used formerly to lower blood-pressure. Toxic doses of hydrated chloral cause a marked vascular dilatation, and it is commonly stated or implied that therapeutic doses also lower the blood-pressure. Any such action, however, is commonly incidental to its narcotic effect and not due to its vasodilator action, which is unimportant except with toxic doses.

Guthrie is credited with having been the first to observe the effects of the nitrites in causing flushing of the face. Lauder Brunton is chiefly responsible for their introduction into therapeutics about 1867, after he had observed the effects of amyl nitrite on a patient who suffered from anginal attacks.

Tracings of the pulse taken by him after the administration of amyl nitrite during one of these attacks do not show any essential difference from tracings of the normal pulse, the amyl nitrite having overcome the vasoconstriction which accompanied the attacks.

The actions of the several nitrites, including amyl nitrite, glyceryl nitrate or nitroglycerin, which acts as a nitrite, and sodium nitrite, are qualitatively quite similar, though they differ somewhat in duration.

The nitrites have little direct action on the higher parts of the brain, except for the dilatation of the cerebral arteries. This is attended with a sense of fulness in the head and diziness, with some disturbance of the special senses, and often with headache.

The effects on the medullary centers are direct and indirect, but it is not easy to determine which of these is the more important in some cases.

The vasomotor centers are certainly depressed after the administration of small doses of the nitrites, but this depression is probably not alone responsible for the vasodilatation which results, especially after large doses. The vessels of the face and neck—the so-called blush area—are affected first, and the vessels of the skin of the upper part of the body in general appear to dilate before the splanchnics, but these also participate in the effects of therapeutic doses.

There has been a good deal of discussion concerning the seat of the dilator action of the nitrites, and some authors attribute the effect almost entirely to the action on the musculature in the vessel walls, while others consider this wholly secondary and attribute the effect mainly to the depression of the vasomotor centers.

The question is of more than purely theoretic importance, because it is frequently stated that the nitrites have an especial action on the coronaries. It seems probable that they have no specific action on the coronaries, but that the benefit which they confer in conditions attended with high blood-pressure is due mainly to the relief of an overburdened heart by diminishing the resistance. Attention has already been called to the physiologic necessity for the coronaries to respond to increased cardiac action with dilatation when other arteries are constricted, from which it is evident that they do not behave toward all agents in the same way that other arteries do.

It is uncertain whether the nitrites have any important direct action on the other medullary centers, though the functions controlled by these centers show active changes. It is sometimes stated that the vagus is depressed, leading to an increase in the heart-rate. The heart, however, responds normally to lowered blood-pressure by an increase in the rate of the beat.[1]

---

* This is the twentieth of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

[1] The tone of the vagus depends to a great extent on the blood-pressure in the medulla, and when this falls, the lowered vagus tone permits of acceleration through the action of the accelerator center. The delicacy of this regulating mechanism in the dog is such that it is extremely difficult at times to cause a notable fall in the blood-pressure by administering amyl nitrite to that animal, the heart becoming much faster with a slight fall. The rabbit lacks this delicate control and amyl nitrite causes a prompt fall of the blood-pressure.

and it is not probable that vagus depression is due largely to the direct action of the nitrites. At any rate, it is important to remember that the heart is not injured by therapeutic doses of the nitrites, since these are used in precisely those conditions in which the heart suffers from overexertion.

After the administration of amyl nitrite the respiratory center behaves as it does during fall of blood-pressure from other causes, that is, it responds to the stimulation of carbon dioxid (or lack of oxygen), and increased respiration results. There is no reason to suppose that the nitrites stimulate the center directly.

The text-books state that enormous doses of the nitrites result in the formation of methemoglobin. This does not occur, however, with doses such as are used therapeutically; it is of no interest to the clinician, except in possible cases of poisoning.

Other smooth muscle beside that of the arterioles is depressed by the nitrites, and spasm of the bronchial muscles is said to be relieved by the fumes from the burning of potassium nitrate mixtures, which contain nitrites.

The nitrites cause venous dilatation, and this probably contributes somewhat to the fall of blood-pressure, by providing reservoirs for the blood.

The nitrites are oxidized in the body and appear in the urine chiefly as nitrates.

In addition to the effects of nitrites which have been discussed, other secondary effects will be observed at times,[2] but these are inconstant, and are to be explained by the differences in the distribution of the blood which are seen at different times. If the renal vessels are dilated to a disproportionately greater extent than those of the general circulation, there may be an increased secretion of urine, but diuresis in such cases is not to be attributed to any direct action of the nitrites on the kidneys.

ACONITE

The actions of aconite are those of its principal alkaloid, aconitin, but tincture of aconite is used much more frequently than the alkaloid, because of the difficulty of obtaining aconitin of constant activity, and because of the mechanical difficulties involved in the use of a drug of such extraordinary potency.

The actions of aconitin on the central nervous system are difficult of analysis, but these consist of stimulation and subsequent depression.

The heat-regulating center (if we may refer to the coordinating mechanism as a center) seems to be influenced by aconitin in the same way in which it is by the antipyretics, and aconite has a distinctly antipyretic action.

The vagus center is stimulated, and Cushny states that aconitin affords one of the best means of obtaining pure slowing of the heart. Fatal doses affect the heart partly through the vagus, and it is stated that larger doses of aconitin are survived if atropin be given than without it.

Aconitin stimulates the respiratory center, but this shows a strong tendency to become depressed, and death from aconitin frequently results from paralysis of the respiratory center. So great is the tendency of aconitin to cause depression that it cannot be used therapeutically as a respiratory stimulant.

Vomiting often occurs late in the state of poisoning, this being due to stimulation of the vomiting center (unpublished experiments).

The direct action on the vasomotor centers does not appear to be constant, and there may be either reflex stimulation or depression, but there seems to be some evidence that vasodilatation is the more common effect of aconitin action.

The effect of aconitin on the heart is due to vagus and accelerator stimulation and to the direct action on the heart itself. There is apparently a brief period during which the heart beats more energetically because of accelerator stimulation, but this is unimportant, and with the slowing from vagus stimulation there is no corresponding increase in the strength of the contractions, so that less blood is expelled from the heart in a unit of time, and in consequence the blood-pressure falls. With severe poisoning from aconitin the heart becomes very irregular; in fact, various forms of irregularity are seen in the exposed heart of an animal poisoned with it, the heart finally stopping in diastole. It is more than possible that aconitin causes a fall of blood-pressure through its combined actions on the cardiac muscle, the vagus center and the vasomotor centers.

Aconitin causes tingling when applied to the tongue or to the skin in such a way that it penetrates to the sensory nerves, and when large doses have been taken this tingling is manifested in the same way as after local application. It is one of the most typical symptoms of aconite poisoning, and usually serves to call the patient's attention to something being amiss in such cases.

Aconite was formerly administered therapeutically to the point of commencing tingling in the fingers. The sensory stimulation is followed by anesthesia, but this action is much less pronounced with aconitin than with cocain, or even than with atropin, to both of which aconitin is closely related chemically.

Aconitin is absorbed rapidly from the alimentary canal, and, to some extent, from the unbroken skin when applied in the form of an oleate or liniment.

Poisoning by aconite is not rare, but less frequent perhaps than formerly, when aconite was widely used for a great variety of complaints.

Absorption takes place so rapidly that there is usually little time for treatment after a fatal dose has been swallowed. Tingling and irritation of the mouth and throat are observed soon after the poison has been taken. This is due to the local action, and soon after the poison is absorbed the tingling is felt in the finger-tips, and later over a large part of the body. Nausea, vomiting and diarrhea may occur. The respiration suffers severely as well as the circulation, and death probably results from a combination of the actions on the heart and the respiration.

Of course, any poison remaining unabsorbed should be removed from the stomach by washing; atropin is said to be antidotal, but it is probably of limited value in most cases, and artificial respiration would be preferable to the atropin action on the respiratory center.

---

2. The question has been raised frequently whether the small amounts of nitrites present in flour bleached by the several processes in common use are injurious to health and whether flour bleached in this way is less digestible than unbleached. There is no evidence that minute amounts of nitrites are injurious, and it cannot be said that the flour so bleached is less digestible than the unbleached, but on the other hand, we are unable to say that small amounts of the nitrites continued over long periods are without deleterious influence on the health, and there still remains the larger subject on which there can be no discussion, that bleaching is often employed for fraudulent purposes.

A single dose of 1 mg. ($\frac{1}{60}$ grain) of atropin may be given, and repeated once if it causes improvement in the respiration or if it fails to abolish the vagus influence on the heart.

The patient is kept as quiet as possible, and heat is applied to the body.

Tincture of aconite probably undergoes deterioration when kept long, and dogs sometimes withstand enormous doses even when these are injected intravenously. It is probable that the fatal dose of pure aconitin for a man is only a few milligrams.

THERAPEUTIC USES

The nitrites are used, as already indicated, for reducing blood-pressure. Amyl nitrite finds its especial field of usefulness in giving relief in attacks of angina pectoris, in which it is often supposed to abolish spasm of the coronary arteries. It seems much more probable that amyl nitrite relieves this distressing and even terrifying condition by abolishing the excessive resistance against which the heart contracts.

It may be used to relieve any pain which is due to arterial spasm, to prevent or relieve epileptic convulsions, and in bronchial asthma.

Amyl nitrite is sometimes used to stop hemorrhage when this results from the rupture of a vessel in the lungs, brain or elsewhere through very high blood-pressure, but it is apt to do harm if the hemorrhage has progressed to the point that the general arterial pressure is already low. Owing to the brevity of its action it is unsuited to those conditions in which a prolonged effect is necessary.

Nitroglycerin is used much like amyl nitrite, but its action is not induced instantaneously as that of amyl nitrite is, and it is therefore employed where a slower and somewhat more lasting action is desired, as in the high blood-pressure of arteriosclerosis and of nephritis, as well as between the attacks of angina pectoris.

It is sometimes used with digitalis with a view to overcoming the reputed vasoconstrictor action of the latter. It has been brought out in the discussion of digitalis actions that this direct vasoconstrictor action is negligible, and that digitalis may actually cause a fall of blood-pressure when this was previously abnormally high.

It is probable that nitroglycerin is seldom of any benefit in influencing the action of digitalis.

Sodium nitrite is used for exactly the same purposes as nitroglycerin, and it probably has no advantages over the latter.

Erythrol tetranitrate (for description see New and Nonofficial Remedies) is used for the same purposes as nitroglycerin, over which it has the advantage of exerting a more prolonged action. It is very expensive, and is said to be even more prone than nitroglycerin to cause severe headache.

The vasodilator actions of alcohol have been referred to; spirit of nitrous ether has a feeble vasodilator action, and is used to promote diuresis and diaphoresis.

In some cases the splanchnics appear to be incapable of dilating in response to the action of the nitrites, and in such cases the slight fall in the blood-pressure, and probably some direct depression of the vagus center, result in such an increase in the heart-rate that the fall is converted into a temporary rise of pressure.

Aconite is used *occasionally* as an antipyretic and diaphoretic in fever patients of sthenic type, or early in other febrile conditions — not late during protracted fevers, such as typhoid. It may be used cautiously when it is desired to reduce the blood-pressure, if the heart is in good condition. There is little scientific basis for its continued internal use in therapeutics.

It is used externally in the form of liniments and ointments for the relief of neuralgias. Absorption may occur from the unbroken skin, and it should be used only with caution. It should not be applied to mucous membranes, from which it is absorbed promptly.

Veratrum viride is sometimes used for the reduction of the extremely high blood-pressure often seen in eclampsia. While good results have been reported in some cases, the action of the drug is not sufficiently understood to justify its use in general practice, and there is little reason to doubt that it sometimes precipitates a catastrophe in this dangerous condition. Veratrum viride is not recognized in "Useful Drugs," nor is it recommended here. It probably owes any popularity which it has to its former exploitation as a proprietary preparation under the name of "Norwood's Tincture."

DOSAGE

Amyl nitrite is commonly used in the form of glass capsules, or "pearls" containing from 0.2 to 0.3 c.c. (3 to 5 *minims*). These are carried about by the patient, and at the approach of an attack one of the "pearls" is broken in the handkerchief and inhaled.

Amyl nitrite is sometimes sold in sealed glass containers holding about 25 gm. (1 fluidounce).[3] These tubes should never be grasped in the bare hand. Before being opened they should be cooled, and wrapped in several folds of a towel loosely; the operator, when filing the neck, should point the tube away from his face.

Nitroglycerin being explosive, is commonly used in the form of the spirit or in tablets. The average dose of spirit of nitroglycerin is 0.05 c.c. (1 minim), which is to be repeated several times daily when it is desired to maintain the effect. It gradually loses its capacity for lowering the blood-pressure, owing to the development of habituation, and the intensity of the headache which it frequently causes is a great disadvantage in its use.

Spirit of nitrous ether, popularly used as a diuretic, has, to a limited extent, the vasodilator action of other nitrites, but is now seldom used. The average dose is 2 c.c. (30 minims).

The dose of sodium nitrite is about 0.05 gm. (1 grain) repeated several times daily. It is always administered in solution, but it is prone to undergo oxidation with the formation of the nitrate; hence only enough of the solution should be prepared to last a short time.

Aconite is almost invariably administered in the form of the tincture, of which the dose is 0.2 c.c. (3 minims) repeated every hour until the desired effect is produced. Smaller doses may be given with correspondingly greater frequency.*

---

[3] The following experience may be of interest: The neck of one of these tubes was filed with the intention of opening it, when it exploded violently; a second tube was cooled in a freezing mixture of salt and ice, and the neck then filed; there was a severe explosion; several tubes were then opened after wrapping them in towels, but in every case explosions of extreme violence resulted. The makers are well-known chemists, but they have been unable to explain the extreme violence with which these tubes exploded.

* Owing to lack of space the materia medica of this group is omitted from The Journal. It will be included when this series is published in book form.

DIURETICS

The secretion of urine may be influenced by drugs in many different ways; hence the diuretics do not constitute a well-defined group, and in fact, few of them are used as diuretics exclusively. Some of the diuretics have been discussed among other groups, and others will be discussed elsewhere.

Sollmann[1] classifies the diuretics as follows:

1. Those acting through changes in the general circulation.
2. Those acting purely by local irritant stimulation of the kidney cells.
3. Those acting by non-irritant stimulation of the kidney cells.
4. Those acting mainly by salt action.

Under normal conditions the rate at which the urine is secreted varies with the volume of blood which passes through the kidneys in a unit of time, but there is a minimum blood pressure (about 40 mm. of mercury), below which the kidneys do not function. On the other hand, intense constriction of the renal arteries causes a diminution of the secretion even though the general blood pressure may remain high.

DIGITALIS BODIES

The actions of the digitalis bodies have been discussed and it is necessary to call attention here only to the fact that they cause diuresis by improving the circulation. There is no evidence that they act on the kidneys directly, and in fact they do not cause diuresis in healthy man, since they do not improve the normal circulation.

VASODILATORS

While our knowledge of the actions of the vasomotor nerves in controlling the circulation is considerable, we do not know much about the changes which drugs cause in the renal circulation under different conditions, unless they induce diuresis, which may be accepted as evidence that the circulation has been improved. But improvement means only a closer approximation to normal conditions, since either vasodilation or vasoconstriction may interfere with the secretion.

We may conclude then that the vasodilators will facilitate the secretion of urine when they abolish an excessive constriction of the renal arteries without causing too great a fall in the general blood pressure, but we are unable to state in what cases this beneficial effect will follow their use. The nitrites and other vasodilators have been employed in many cases in which they could hardly be of benefit, for example, they have been recommended frequently to overcome the vasoconstrictor action of the digitalis bodies, but, as we have already pointed out, the *direct* vasoconstrictor action of therapeutic doses of the digitalis bodies is wholly negligible, and when an improvement in vascular tone follows their use it is due to the general improvement in the circulation, and does not call for vasodilators.

It is hardly probable that the vasodilators can often have any important action in promoting diuresis, but the indications for their use in any case may be deduced from the discussion of their actions.

The drugs of the caffein group influence the general circulation but their most pronounced diuretic action is exerted on the kidney directly.

IRRITANTS

The second class of drugs—those which act through their local irritant action on the renal cells—embraces the volatile oils, which have been mentioned under urinary disinfectants, and certain glucosidal bodies, such as scoparin, and some others which are not used therapeutically for their diuretic action.

The most important drug usually classed among the irritant diuretics is calomel. There is no question that large doses of calomel are capable of causing renal irritation, hence caution is urged when it is employed in nephritis, and some authorities state that it should not be used when there is the least suspicion of nephritis. That view would appear to be extreme, however.

An entirely different theory has been advanced recently to account for the diuretic action of calomel. It causes increased peristalsis in the small intestine resulting in a lessened absorption, and consequently in the emptying of a larger amount of fluid into the colon than normally. It is explained that calomel does not affect the large intestine markedly, and the excess of fluid in the colon undergoes rapid absorption. In the meantime the composition of the blood has been restored to the normal through the withdrawal of fluid from the tissues to compensate for that excreted into the small intestine, and this rapid absorption of fluid from the large intestine induces hydremia and consequent diuresis. It is urged that the copious diuresis which accompanies the absorption of small amounts of calomel prevents the latter from exerting its irritant action on the renal cells.

It is a matter of common experience that calomel diuresis is attended with greater improvement in the condition of dropsical patients, than is seen when it causes the removal of water by purgation.

There is no apparent advantage in securing the absorption of water from the colon only in order that it may be excreted by the kidneys, hence we must suppose that the advantage is due to a milder action whereby the sudden removal of a large amount of fluid from the circulation is avoided.

The combination of opium and calomel causes diuresis more certainly than does calomel alone, and this is explained on the basis that the delayed peristalsis permits of a greater absorption of calomel, or according to the view of calomel action just discussed, it permits of a greater absorption of water from the large intestine.

WATER

Several investigators have found that a given amount of water administered by the mouth causes a greater diuresis than an equal amount injected intravenously or subcutaneously. It has been suggested that some substance which is actively diuretic, is absorbed with the water from the intestine, and that it is the absence of this hypothetic substance in the circulation which accounts for the slighter diuresis when the water is injected intravenously. It is probable that the diuretic action of calomel may stand in relation to this observation.

CAFFEIN GROUP

The drugs of the caffein group are the only ones of importance which induce diuresis through their non-irritant stimulation of the renal cells.

We have called attention to their influence on the heart, and on the vasomotor system, and it remains to discuss their specific action on the renal cells.

---

[1] Sollmann: Pharmacology, Philadelphia, W. B. Saunders Company, 1906, Ed. 2, p. 546.

It is generally held that they act on the tubules, stimulating them to increased secretion, but there is another theory of their action which is diametrically opposed to this view, according to which caffein inhibits the capacity of the tubules for reabsorbing water, with a consequent increase in the amount eliminated.

Whichever theory is correct, the essential fact for the clinician is that caffein and theobromin act on the kidneys and do not cause irritation, hence they may be used in the presence of nephritis.

It is sometimes maintained that these agents cause a specific dilation of the renal vessels, but the vessels of every organ dilate when it begins to function more actively, and it is impossible to say whether the renal dilation is the cause or effect of renal activity.

OTHER MEANS OF CAUSING DIURESIS

The rate of secretion of urine varies with the viscosity of the blood, and anything which causes water to pass into the circulation tends to promote the secretion of urine. This may be accomplished by causing water to be absorbed from the body tissues or from the alimentary tract.

The absorption of tissue fluids into the circulation may be accelerated during health by the intravenous injection of a saline solution which has a higher concentration than the blood. The renal cells offer little resistance to the passage of sodium sulphate, and when a 2 per cent. solution is injected intravenously, tissue fluid passes into the circulation and active diuresis is induced. This is one of the most active diuretics at our command, and may be depended on to hasten the elimination of those poisons which are excreted by the kidneys. Obviously, this method is only suited for emergencies.

Venous stasis favors the passage of water from the blood into the tissues, and conversely, the relief of venous stasis is commonly followed by the return of the water from the tissues into the circulation, with the resulting hydremia and diuresis.

Even a comparatively small initial change of this sort may institute diuresis with the ultimate elimination of enormous quantities of water with progressive improvement in the circulation and relief of the stasis; hence any drug which causes improvement in the gen-
mally nigenlation in dropsical conditions will act as a

sive, and is said to be even more prone than nit the
glycerin to cause severe headache. ge

The vasodilator actions of alcohol have been referred to; spirit of nitrous ether has a feeble vasodilator action, and is used to promote diuresis and diaphoresis.

In some cases the splanchnics appear to be incapable of dilating in response to the action of the nitrites, and in such cases the slight fall in the blood-pressure, and probably some direct depression of the vagus center, result in such an increase in the heart-rate that the fall is converted into a temporary rise of pressure.

Aconite is used occasionally as an antipyretic and *diaphoretic in* fever patients of sthenic type, or early are obvious. When the circulation is impaired and water accumulates in the tissues, it causes distress, and its removal becomes imperative. This may be accomplished in part by sweating and purgation, but diuresis affords the most satisfactory method of disposing of the accumulations when the kidneys are capable of functioning normally.

It is not feasible to consider all of the therapeutic indications for diuretics, and only a few of them will be discussed here.

We do not know enough about the toxic substances (toxins) which are formed during disease and the best method of securing their elimination to enable us to state just what measures should be employed, and therefore we do not know to what extent the use of active diuretics will prove beneficial in many cases. We know that certain vegetable poisons at least are excreted practically unchanged in the urine, while others are decomposed to a greater or less extent before they are eliminated, and still others are removed from the circulation by the liver, and exert practically no effect on the kidneys, and their elimination is practically unaffected by diuresis.

Our knowledge of the fate of many of the vegetable poisons is fragmentary, and we are often unable to state whether they are eliminated by the kidneys, or by the liver, or are destroyed in the organism.

Even in those cases in which we know that a poison is eliminated by the kidneys, we are seldom able to state whether it is excreted through the glomeruli or through the activity of the tubular epithelium, hence we do not know which of the diuretic drugs is to be preferred in a given case. Fortunately, diuresis, however induced, appears to favor the elimination of many of those poisons which are excreted through the kidneys, and the necessity of choosing one diuretic rather than another does not appear to be pressing, and in cases of acute poisoning by a drug such as strychnin, which is excreted mainly by the kidney, and when the necessity of securing its rapid elimination is urgent, one's efforts should be directed toward inducing copious diuresis by the most effective means at hand.

When poisons which are capable of inducing nephritis have entered the circulation, it seems probable that we should secure the largest possible flow of blood through the kidney vessels, as well as the most copious diuresis; hence caffein and theobromin, which are said to cause a specific dilation of the renal vessels, probably deserve consideration in addition to other diuretic measures.

It is surprising how little attention has been paid to the possibilities of extreme diuresis and flushing of the kidneys to the maximum in cases of poisoning with mercuric salts, which have become all too common of late, but it is not to be understood that this subject has been wholly neglected, and diuresis does play an important rôle in the treatment in such cases. We do not believe that the possibilities of the treatment have been appreciated, however, just as the possibilities of the elimination of strychnin during intense diuresis have been overlooked, even though every text-book mentions diuretics as a part of the routine treatment such cases.

The choice of diuretics in a given case is often piric though there are certain conditions which nand a definite method of procedure.

When there is an accumulation of water in the tis- (dropsy) due to the faulty action of the heart and its failure to maintain an adequate circulation, the digitalis bodies are of the first importance, and their action may be supplemented advantageously by that of caffein. Since it is necessary to rid the body of water it would evidently be improper to secure diuresis through the administration of large amounts of fluid. The different drugs of the digitalis group contain irritant principles and it is barely possible that some of these may induce diuresis after the manner of the second class mentioned above, that is, those acting purely by their irritant action on the renal cells, but, on the other hand, the absence of diuretic action during health from these agents, and the fact that they do not cause diuresis in dropsical conditions unless they improve the circulation through their cardiac actions, is strongly indicative of their acting as diuretics only through the changes in the general and renal circulation. The irritant digitalis principles are probably excreted almost entirely through the liver, and when they are excreted through the kidney this appears to take place so slowly that they are never in sufficient concentration to cause severe irritation. At any rate the digitalis bodies do not cause serious renal irritation and they are used in the presence of nephritis.

The action of the digitalis bodies may be supplemented by diuretics which cause dilation of the renal vessels (caffein), or by those which cause hydremia (calomel, potassium acetate).

Just as digitalis bodies are indicated when the cardiac action is impaired, so they are contra-indicated when the heart beat is normal, and in such cases dependence should be placed in drugs which diminish the viscosity of the blood, or those which act on the kidneys directly when diuresis is desired.

There is seldom any special indication for the use of the volatile oils as diuretics alone, but they are sometimes used in small doses which produce only a mild stimulation of the kidney cells.

The injection of physiologic salt solution commonly causes a marked diuresis, but the kidney may become resistant to the passage of sodium chlorid as the result of continued administration or under pathologic conditions, in which case the administration of salt leads to a diminution of urinary secretion. It then becomes necessary to reduce the ingestion of salt to a minimum. Attention has been called recently to the slow intravenous injection of hypertonic solution of glucose when sodium chlorid is contra-indicated.

Venous engorgemer[illegible] minal veins which results from [illegible] interferes with the renal circulation by retarding the outflow, and, as is very well known, anything that interferes with the free outflow from the renal veins interferes with the secretion of urine. Hence anything which relieves the venous stasis promotes the secretion of urine.

Active cathartics which remove a large amount of water may suffice to relieve the interference with the renal circulation. In like manner dropsical accumulations may interfere mechanically with the venous return and thereby lessen the secretion of urine, and in an analogous manner the purgative sometimes affords relief by removing the water which presses on the veins.

Clinicians often experience great difficulty in removing accumulations of fluid in patients who suffer with renal insufficiency. The retention of urea in nephritis is so well known as to require no further comment.

Saline diuretics and drugs of the caffein group are said to be best for use during chronic nephritis.

DOSAGE

The dosage of the digitalis bodies has been discussed in the article dealing with cardiac drugs.

The dosage of caffein and theobromin for inducing diuresis is commonly limited by its actions on the heart and central nervous system, especially in the case of caffein by its tendency to produce wakefulness, and in the case of theobromin by its action on the heart.

The diuretic dose of caffein is usually given as 0.3 gm. (5 grains) but the drug is commonly given up to the limitations imposed by its side actions. It may be repeated about three times a day. Theobromin is given in about the same amounts, but owing to the more rapid action it may be repeated about four times a day.[2]

The volatile oils are seldom administered alone for their diuretic action, but they are sometimes used in the form of infusions, or other preparations of drugs which contain them.

The dose of potassium acetate is about 2 gm. (30 grains). It is commonly used when it is desired to increase the urine and render it alkaline, and the dose may be repeated every two or three hours until the desired object is attained. It is converted into the carbonate, in which form it is excreted largely.

Calomel is given in doses of from 0.1 to 0.2 gm. (from 1½ to 3 grains) several times daily when it is desired to cause diuresis. Since such doses cause diarrhea in most cases, it is often advised that opium be administered with it in sufficient amounts to prevent active purgation. This interferes with the evacuation of large amounts of water, and does cause diuresis in the manner described, but it is probably better to use smaller doses of calomel, and avoid the necessity of using opium. In many cases the removal of even a small amount of water by purgation will suffice to inaugurate an increased secretion of urine, and with a mild action one avoids the depression which is such an objectionable feature of violent calomel purgation. Small doses of calomel often cause purging with little more discomfort than accompanies a normal movement. The severe depression which accompanies calomel purgation is probably due in a large measure to the determination of an excessive amount of blood to the splanchnic region as the result of active intestinal secretion. Moderate action is not accompanied by this excessive activity of the intestinal glands and the resulting depression.

It seems probable that the combined use of digitalis, calomel and caffein or theobromin would be better than calomel with opium, except when the opium is needed for its other actions.*

(To be continued)

---

[2] It seems probable that theobromin may be administered conveniently in the form of cocoa in sufficient amounts in many cases. It is often objected that this requires the administration of too much water, but every patient must have some fluid every day, and since cocoa should be made with *milk only*—*not* with water—there is no apparent reason why the cocoa should not be administered with the milk which forms an important part of the diet as a rule in such cases. The better class of powdered cocoas contain about 1 per cent. of theobromin, hence 10 gm. of powdered cocoa, sufficient for one cup, would contain 0.1 gm. (1½ grains) of theobromin. If desired, the theobromin administered in this way may be supplemented by theobromin or the theobromin and sodium acetate or salicylate. An advantage in the use of cocoa in this way is the reduction of the amount of sodium salicylate or acetate which it presents, and the lessened gastric disturbance.

SENSATIONS OF GASTRIC ORIGIN

The classification and analysis of our sensations meet serious obstacles when we attempt to unravel the nature of those feelings through which a knowledge of the condition of the body and perhaps of ourselves as distinct from the external world is acquired. There is a group of organic sensations of movement and position, of pain, fatigue and less definite sensations of the visceral organs, which furnish subjective information regarding ourselves as things apart from the objects which surround us or the changes which excite our exterior senses. Important as the psychologic significance of these sensations projected into the interior of the body is in the way of entering into and qualifying our judgments, the subject does not lend itself readily to popular discussion. Aside from vague suggestions of ill-defined localities which are furnished by the pain sense, the sensory data derived from the interior of the body are exceedingly meager at best.

The inaccuracy of localization which pertains to the sensations associated with the visceral organs is in part complicated by the reference of pain arising from them to other parts of the body, notably to certain areas of the skin. Experience teaches that the stomach is not sensitive to touch; otherwise we should all be more familiar with this organ than we are. There are times, however, when sensibility of some sort is present. What is the solution of this seeming paradox?

Professor Carlson[1] of the University of Chicago concurs, with other investigators who have examined cases of fistula in the human stomach, in the conclusion that stimulation of the normal gastric mucosa does not produce tactile sensation. Gently touching or striking the mucosa with blunt objects produces no sensation. The indefinable feeling noted when more vigorous manipulation is employed is not like touch or pain or hunger, and is presumably associated with some outlying visceral part. Carlson believes that the sensation of pain cannot be produced from the normal gastric mucosa by any stimulation confined to the mucosa itself. Pinpricks or incisions of the normal mucosa do not seem to affect consciousness in any way. It does not follow that pain may not be caused by the stimulation of the hypersensitive mucosa. It is suggested that the gastric pain accompanying excessive inflation, gastric ulcers and chronic obstruction is due to the mechanical stimulation of hypersensitive nerves or nerve endings in the muscularis or submucosa by excessive distention or contraction. The nature of gastric hunger pains has already been discussed in THE JOURNAL.[2]

With respect to the recognition of temperature changes, the conditions in the stomach seem to be somewhat different. The evidence suggests that the mucosa is endowed with heat and cold nerve endings. The sensibility appears to be of the type which Head has termed protopathic, that is, of somewhat indefinite and "affective" character rather than "epicritic" and accurately localized. These fibers are undoubtedly more abundant and readily stimulated in the throat and esophagus than in the stomach; but the temperature sensations initiated by touching the gastric mucosa directly through a fistula with hot or cold solids cannot be referred to the esophageal membrane or to the skin of the abdomen. It is an interesting fact that heat and cold sensations are not confused, and that according to several investigators the cold sensation seems to be more distinct and better localized than the heat sensation.

The sensation of fulness does not originate in the mucosa of the stomach.[3] Its main source is the tension exerted from within on the circular muscular fibers of the stomach. A certain amount of tonus relaxation of the organ must be present before tension or pressure of the walls of the stomach produces the sensation of fulness.

Carlson has maintained for some time that hunger and appetite are qualitatively different sensations.[2] The sensory apparatus for hunger is distributed in the stomach wall and is stimulated by a certain type of contractions of the empty stomach. When foods or liquids are taken into the mouth and swallowed in the normal way, their main influence on appetite is via nerve endings in the mouth. In fact, the latter is so prominent that only by excluding it are we able clearly to distinguish the gastric factor. The memory factor in appetite is therefore preeminently gustatory and olfactory. Nevertheless the recent observations[1] on a subject with a gastric fistula indicate that chemical, and possibly mechanical, stimulation of nerve endings in the normal gastric mucosa gives rise to a sensation identical with appetite. This is the basis for the conclusion that the mucosa is endowed with a "protopathic" appetite sense. In weighing the uncertainties of such statements it must be remembered that they represent the results of subjective analysis, a debatable mode of investigation enforced by the necessities of the problem.

WAR EXPERIENCES WITH INFECTED WOUNDS

The treatment of the bacterial infections of projectile wounds, founded on the experiences in the present war, forms the subject of an interesting memorandum[1] bearing the signatures of Colonels F. F. Burghard, Sir W. B. Leishman, F.R.S., Sir B. Moynihan and Sir A. E. Wright, F.R.S. The memorandum is issued for the guidance of members of the English army medical service in the treatment of wounds during the war, and it is expected, as soon as certain researches are completed, to follow it with additional memoranda on the employment of antiseptics and vaccines.

Among the most interesting observations made with regard to wounds, and particularly deep, penetrating wounds as made by shells in this war, is the notable difference between the reaction of sailors and soldiers. Sailors with the most severe type of wound, ragged, irregular, with uneven surface produced by herniated muscle and retracted severed fibers, usually have recovered promptly.[2] Soldiers suffering from even slight wounds have often had them contaminated with bacilli from the soil, particularly the anaerobes. This is a trench war; many of the trenches are dug through cultivated fields, and soldiers often cannot be removed from them for many hours after being wounded; contamination becomes almost inevitable. Large penetrating wounds made by shells under such circumstances have been particularly slow to heal, and septic complications have been frequent, severe and only too often fatal.

It was said at first that the sailors recovered promptly and satisfactorily in spite of the fact that many of them were subjected to immersion in cold sea water for from half an hour to an hour or more. Notwithstanding the shock thus inflicted, the reaction both in constitution and wound healing was excellent. Now the commission recommends the bathing of wounds with hypertonic salt solutions like sea water. Probably the exposure to sea water was actually remedial in its effects because the flow of lymph and serum induced in the wounded tissues actually obviated septic sequelae. The practical directions are:

> "For ordinary use, the best application will be a 5 per cent. solution of common salt combined with 0.5 per cent. citrate of soda to render the lymph incoagulable. Where citrate of soda, or a similar decalcifiant is not available, a simple 5 per cent. solution of salt will serve. Sea water, this being equivalent to a 2.5 per cent. solution of salt, may also be employed. In dealing with dry and infiltrated wound surfaces, stronger solutions of salt (up to 10 per cent.) will be found to resolve the induration and to clean up the wound surfaces much more quickly than weaker solutions."

Where the wounds are deep and open, the simplest procedure is to pour in hypertonic salt solution and then plug lightly with gauze. Superficial wounds may be dealt with by laying on gauze thoroughly soaked in the solution. As these measures produce a very free flow of fluids from the wound, care must be taken to keep the bed and clothing from becoming perilously or even uncomfortably damp; therefore the limb should be wrapped in water-proof material. The memorandum adds that an application of petrolatum will prevent irritation of the skin and stinging on freshly cut skin surfaces. It is interesting to realize that this suggested method of treatment is actually a reversion to the idea of "drawing something out" of the system which used to be so familiar in connection with the use of poultices in the older generations, though, of course, poultices were usually applied to unbroken surfaces. The memorandum speaks of the "drawing agent" having done its work "as soon as it has checked the spreading invasion of the tissues, and cleaned up the dry and indurated wound surface and this last has clothed itself in bright coral red granulations. The hypertonic salt solution may then be replaced by some simple dressing."

Antiseptics have lost their prestige, but are now recommended because they help in the destruction of bacteria of various kinds in tissue débris which might cause infective processes in others or contaminate the hospital generally. If this precaution were omitted, infective microbes would inevitably be carried from one wound to another, and by such "passaging" there would almost surely "be bred out in the hospitals very virulent strains of microbes which would as in pre-Listerian days induce all manner of fatal septic infection. . . . Up to the present, experiment has not furnished anything in confirmation of the idea that the introduction of antiseptics into wounds would be likely to contribute to the arrest of suppuration." In a word then, while antiseptics used to be employed for the sake of the individual to whom they were applied, with the belief that they facilitated wound-healing, they are now recommended only because of the protection that they afford to others.

In conclusion, the memorandum suggests that when wounds are heavily infected, the ideal method of treatment, if only it were always practicable, would be immersion in a bath or continuous irrigation with some aseptic or mildly antiseptic fluid. When this continuous bath or, according to the conditions of the cases and the circumstances of the treatment, "the lymph lavage" induced by hypertonic salt solution has brought the infection under control, what remains of the infectious process may very often be extinguished by freely exposing the open wound to the air. In other words, two of Nature's simplest and most abundant materials, sea water and air, have come back as adjuvants in surgery. There has long been a tradition among sailors that washing wounds with sea water did them good, and on the farm, salt solution has often been employed in the treatment of wounds both of animals and of men. The feeling usually was that this old-time tradition probably had little basis of value in it, though now the experience of a great war would seem to indicate that the acute clinical observation of the older generations has enabled them to realize the value of applications of salt solution. As the true reason was misunderstood, their use gradually went out, or became limited only to popular medicine. As a reversion to older ideas in many particulars, this memorandum is significant in the history of medicine.

INDOOR HUMIDITY

There is a widespread and growing belief in this country that the problems of ventilation are in need of exhaustive investigation. Some of the aspects of this subject, and particularly their bearing on hospital ventilation, have been discussed in detail in a series of papers in The Journal.[1] Physiologic research has brought about a new attitude in regard to what constitutes "foul air." The chemical composition of the atmosphere, its relative content of oxygen, carbon dioxid and other gaseous ingredients, are now of less concern to the hygienist than are certain other factors formerly looked on as somewhat incidental. The movement of the air, and its temperature and humidity now likewise call for careful attention and analysis. To a certain degree these features are interrelated and may properly be considered together.

Inasmuch as the temperature of the body is regulated by the loss of heat through evaporation of water from the lungs and skin, obviously the humidity of the environment of the body is of no small importance. The term "relative humidity" is used to express the ratio of the moisture actually present in a given space to the maximum amount which this volume can contain at the same temperature. At a temperature of 15 C. (59 F.) and with a relative humidity of 75 per cent. — a high figure — Pettenkofer and Voit estimated the loss of water by the lungs at 286 grams, and from the skin at from 500 to 1,700 grams daily. This will give some idea of the magnitude of the effects here concerned. If the relative humidity be increased, there will be a hindrance to the escape of water from the body; and when this condition of high relative humidity is combined with a high temperature of the air, the heat is far more oppressive than when the air is dry and allows free evaporation. Conversely, a cold, moist atmosphere may also be distressing.

The complexity of the question of humidity is well exemplified by the statement that very humid air, on the one hand, may prevent the comfortable escape of body heat by evaporation, whereas very dry air, especially when warm, is said to affect the mucous membranes injuriously. The foremost need at the present time is a mass of facts — something definite and tangible to guide the ventilating engineer. It is commonly stated that the air in our houses is too dry in winter, especially in cold weather. An American physicist[2] has called attention to the fact that most of the current household devices for humidifying the air of houses heated by the hot air furnace are entirely inadequate for this purpose. According to his calculations, a house containing 17,000 cubic feet of space would require, for a relative humidity of 40 per cent. at 70 F., with air already containing 20 per cent. humidity and changed once an hour, about 15 gallons of water a day. Rarely will the familiar water pans of American furnaces evaporate more than 2 or 3 gallons daily — hardly enough to raise the humidity 5 per cent.

Professor Ingersoll[2] of the University of Wisconsin has rarely found a humidity of less than 20 per cent. in buildings examined by him. Even allowing for moisture furnished by the exhalations of occupants and for such occasional sources as cooking operations, he maintains that many gallons of water must be evaporated daily in a moderate-sized house in cold weather to secure even 40 per cent. humidity. The latter figure is less than that given by medical writers as an ideal value. The relative humidity of outside air not infrequently passes the 80 per cent. level. Ingersoll found that when a humidity of 50 per cent. was produced by special devices, the condensation accompanying this value in cold weather proved unbearable. He concludes that for a temperature of about 70 F., which our heated rooms approach in winter, the ideal indoor humidity for winter in a climate such as that of Wisconsin is from 40 to 45 per cent. Seventy per cent. would mean the atmosphere of a steam laundry. According to Ingersoll, any recommendations of this value are either based on pure theory or else are founded on measurements with older forms of unreliable and inaccurate apparatus. Precisely wherein the hygienic advantages of a relative humidity of even 40 per cent. lie remains to be explained.

THE "LAW OF ANTICIPATION"

Numerous statistical studies of the inheritance factor indicate that insanity is gradually increasing. This increase has been attributed not alone to the more intense strain of modern life, but also to alleviation or temporary cure of mental derangements by appropriate treatment, thereby giving the mentally unfit a greater chance for procreation.

In contrast to these notions stands Mott's[1] "law of anticipation," derived from the study of a series of 217 pairs of father and offspring and 291 pairs of mother and offspring in which two or more members of the same family had been inmates of London county asylums. He found insanity appearing in 2 per cent. of the fathers and 4 per cent. of the mothers before 25 years of age, whereas among the offspring, 44 per cent. of the cases occurred before 25 years of age. The average age of onset of insanity was 50 years in the parents and 26 years in the offspring. Thus there was an antedating or anticipation of twenty-four years, the disease occurring, on the average, twenty-four years earlier in the children than in the parents. This so-called "law of anticipation" implies that when children of the insane become insane, they do so at a much earlier age than did their parents. They are also said to suffer from a more intense form of the disease. Mott lays great stress on this as Nature's way of ending or mending an unfit stock, and believes that there is a diminishing risk of the child of an insane parent becoming insane after he has passed 25 years. He even goes so far as to advise offspring of insane parents to marry if at 25 years of age they are mentally sound.

If the "law of anticipation" is a fact, it is evident that much of the present comment on the increase of insanity is unfounded and that many of the problems now confronting eugenists will, through Nature's provision, care for themselves. Since Mott's findings are contrary to conclusions drawn by many other statisticians, Heron[2] has undertaken a careful study of the method of compiling and the interpretation of these data.

He found that cases of insanity occurring before 20 years of age invariably appeared in the tables, whereas, many instances of insanity occurring in the offspring at 40 to 60 years of age escaped the records. Thus a false antedating results. No allowance was made for the mentally normal, at the time the tables were compiled, who in later years became insane. By directly comparing parent and child, one group, the parents, has been limited to over 20 years of age, making a marked error in favor of anticipation. Heron studied this manner of anticipation by means of the family histories of some of the ruling houses of the eighteenth century. In these records, every member of the entire family is accounted for. Among the fathers, none died under 30 years, while 87 per cent. of their children died under that age. The average death age of the fathers was 62, of the children 10, an anticipation of fifty-two years. None of the 294 fathers died before 20, but 106, or 36.1 per cent., of the 294 first-born children died before that age. This manner of selection, similar to Mott's, limits the age of the parental group to over 20 years, while more than one third of the offspring die under 20. This fallacy may be removed by contrasting the death rate of the fathers with that of the first son to marry and have a child. In 213 such instances, scarcely a year separates the age at death of father and son. Thus by removing artificial selection, all anticipation disappears. Further mathematical evidence tends to disprove the possibility of a "law of anticipation," and one must believe that such a law is not based on fact.

Mott's advice concerning marriage of offspring of insane parents has been criticized as unsound. Of the 500 offspring studied by him, 44 per cent. became insane before reaching 25 years of age. If 44 per cent. become insane before 25, 56 per cent. must become insane after this age, and therefore marriage after 25 is of greater risk than before.

The rise and fall of the "law of anticipation" serves as an illustration of fallacies which may occur in statistical studies. In the future such mistakes will happen less frequently since undoubtedly, twenty years hence, statistics will be a science unto itself and dealt with only by trained men.

PASTEURIZATION OF MILK AND THE COLON BACILLUS

Although the pasteurization of milk has become a familiar process in various parts of the United States and is highly lauded in many quarters as an admirable safeguard of the health of consumers, there still is considerable misconception regarding the results actually accomplished. The real function of pasteurization, that is, its actual effect on the milk involved, is not understood so adequately or accurately as it ought to be. Those least conversant with the underlying facts often believe that the procedure destroys all the micro-organisms present in raw milk; the results attained are confused with what is attempted in complete sterilization of milk by more vigorous methods. The more rational assumption, on which the current practices in general are based, is that pasteurization of milk, by heating it to a temperature of from 60 to 63 C. (140 to 145.4 F.) and holding it at this temperature for from twenty to thirty minutes, serves to destroy any bacteria of diseases regarded as transmissible by milk. The use of higher temperatures for shorter periods is now more generally avoided because it is believed that undesirable chemical changes are more likely to take place in milk treated in this way, and more especially because higher heating destroys an undue proportion of lactic acid bacteria, while the spores of certain micro-organisms which decompose the proteins of milk are not destroyed. As a result, the milk may subsequently become unwholesome from putrefactive change before it becomes sour as a result of the acid-forming bacteria.

Realizing, then, that pasteurization is never expected to destroy all bacteria in milk, one is prompted to ask what margin of safety against survival of undesirable living organisms remains at the temperatures and during the periods currently advised for heating the milk. It is said that the presence of colon bacilli in pasteurized milk is generally interpreted as meaning either that the milk was not properly heated or that it was reinfected after pasteurization by careless handling. This interpretation is based on the low thermal death point of cultures of *Bacillus coli.* In the laboratories of the Dairy Division of the Bureau of Animal Industry at Washington, Ayers and Johnson[1] have ascertained the thermal death point of many cultures of colon bacilli isolated from numerous typical sources of contamination, such as the excrement of man and cattle, flies, milk, cream and cheese. The duration of the heating was fixed at thirty minutes for all the trials. At 60 C. (140 F.), the lowest pasteurizing temperature, ninety-five out of 174 cultures examined, or 54.59 per cent., survived; at 62.8 C. (145 F.), the usual temperature for pasteurizing, twelve, or 6.89 per cent., survived. One culture was not destroyed at 65.6 C. (150 F.) on the first heating, but in repeated experiments it was always destroyed. There is a marked difference in the effect of heating at 60 C. and at 62.8 C. Although there is only a difference of 2.8 degrees C., or 5 degrees F., 87.3 per cent. of the cultures which survived at 60 C. were destroyed at 62.8 C.

It is important from a practical standpoint to learn that 62.8 C. maintained for half an hour is a critical temperature for most colon bacilli. It seems desirable, however, to emphasize the fact that though there is a low "majority thermal death point," a few cells often may survive this. Under the circumstances pointed out, the thermometer needs careful watching, and the pasteurization process calls for intelligent execution in order to produce dependable results. The presence of a large number of colon bacilli immediately after the heating process may indicate improper treatment of the milk.

The government bacteriologists have reached the conclusion that if milk is pasteurized at a temperature of 65.6 C. (150 F.) or above for thirty minutes, they would not expect, from their results, that any colon bacilli would survive. Consequently, under such conditions the colon test for the efficiency of pasteurization may be of value. It must be remembered, however, that a study of more cultures may reveal strains of colon bacilli that are able to survive this and even higher temperatures.

THE COAGULATION OF THE BLOOD AFTER HEMORRHAGE

Variations in the clotting power of the blood are encountered in diverse manifestations of practical medicine. Not infrequently they are occasion for uncertainty and annoyance, particularly when conditions arise in which an inhibition of coagulation accompanies some hemorrhagic diathesis. Until the physiologic factors concerned in the coagulation of the blood are more clearly understood, it is almost unwarranted to expect any real progress in the management of the often serious situations created by certain types of uncontrollable hemorrhage. Empiric experience has served as a guide in the past, and the remedial procedures instituted have as a rule been local and palliative rather than fundamental and permanent in character.

The coagulation of the blood has formed the subject of intensive study on the part of physiologists and biochemists for decades. Even the most recent literature in this field abounds in many contradictory statements, irreconcilable observations and obscure points. It calls for no small degree of scientific courage at the present moment to venture an attempt at a comprehensive summary or a tenable theory. The variables are still too numerous and complex to fit into any complete hypothesis yet offered. So long as the experts cannot agree, the physician of today may be excused if he fails to understand the obscure language in which the coagulation phenomena are currently described. The growth of scientific nomenclature is not always a guarantee of progress in the elucidation of the problems of science.

In spite of the confusion, there is an accord on certain fundamental features. Two factors, which we may call fibrinogen and thrombin, unquestionably play a part in the coagulation of the blood. There is a growing objection to the older theories which regard this process as essentially enzymatic in nature. Thrombin, which is somehow formed from a precursor, prothrombin, reacts with fibrinogen to form the fibrin of the clot. According to Howell, the non-coagulability of circulating blood depends on the fact that an inhibitory substance, antithrombin, prevents the activation of the prothrombin into thrombin.

From a practical standpoint in medicine it is of no small moment to learn clearly what substances actually act as accelerators or inhibitors of coagulation. One need only recall the predicament offered by the slow clotting of the blood in hemophilia to gain some appreciation of what might be accomplished if the factors were thoroughly understood. Little by little, however, useful progress is being made. An illustration of this is afforded by a recent study of the effect of rapid progressive hemorrhage on the factors of coagulation.[1] It has long been known that the coagulation time of the blood is decreased under the condition noted.[2] This is, indeed, an advantageous adjustment for the organism. In a search for quantitative alterations in the different factors of coagulation corresponding to the decrease in coagulation time after hemorrhage,[1] it was discovered that the antithrombin decreases in amount and remains practically constant when the coagulation time is unchanged. Under conditions of diminished coagulability of the blood an increase in its antithrombin has been demonstrated; but this newer research is regarded as the first instance in which there has been reported a positive decrease in the antithrombin content of the blood.

Current Comment

A RARE ZOOPARASITE IN MAN

The rarities and novelties of medical experience almost always embody some features of interest quite aside from the immediate practical questions which they involve. When cases of tropical disease are discovered in the temperate zones, the problem of their origin and distribution is inevitably suggested. With the means of communication between the Orient and America improving every year, it is not surprising to learn that disease-producing agencies heretofore unknown among us should follow the easy paths of commerce. These reflections are awakened by the first reported American case of infection with the larval cestode, *Sparganum mansoni.* Somatic teniasis, due to infection with the larval stage of tapeworms, is not a frequently observed condition. Among the different types, hydatid disease, due to infection with the larval *Echinococcus,* and cysticercosis associated with the presence of the larvae of *Taenia* are known far better than the infection with the bothriocephalid larvae of the species *Sparganum mansoni.* Although this larval tapeworm was discovered in 1882, all of the cases of human infection with the zooparasite hitherto reported have concerned persons either living in the Far East (China and Japan) or those who have presumably traveled there. The parasite lodges in various tissues of the body, and is said to show a tendency to wander from one locality to another. The host is not known, so that preventive measures cannot intelligently be followed to avoid infection. When the parasite presents itself to view, as is sometimes the case in the urinary passages, it can usually be removed mechanically. In other cases, when the worm locates in superficial swellings of muscle or connective tissue, surgical treatment must be employed. It was the latter procedure which led to the discovery of the larval *Sparganum* in a breast tumor by Dr. Moore[1] of Houston, Texas. The fact that the patient had never been out of the borders of the United States at the time when the worm, measuring 21.5 cm., was removed from a tissue mass near the nipple, presents a new feature in respect to the geographic distribution of this species of parasite.

THE POISONOUS PRINCIPLE IN WATER HEMLOCK

Among the poisonous plants of which the toxicologic agent has not heretofore been classified with any well-defined chemical group, the water hemlock has furnished many victims. Nine or ten species of *Cicuta,* belonging to the Umbelliferae, or parsley family, have been recorded as occurring in this country. They are, of course, to be clearly distinguished from the spotted hemlock (*Conium maculatum*) of Socrates fame, which is a different genus. The harmful results from eating the roots of the water hemlock have not been confined to domestic animals, among which the mortality has at times been reported to be very high. Two decades ago it was not uncommon to read of severe intoxications in man usually owing, it is said, to a confusion of parts of the plant with parsnips. One author has collected thirty-one cases of poisoning by *Cicuta,* of which number fourteen were fatal. Suicides among Indians, caused by eating the roots of the plant, have also lately been reported. The European pharmacologist Boehm prepared a crude product from the water hemlock and gave the name "cicutoxin" to it. Tested toxicologically, this substance provokes symptoms similar to those which have been described in the poisoning of man by eating the roots. There usually are tremors followed by tonic and clonic spasms. Paresis of the extremities appears, and finally there may be full paralysis and death. It has been supposed that the poison acts specially on the medulla, while the brain and spinal cord are only secondarily affected. At the Nevada Agricultural Experiment Station in Reno, Jacobson[2] has reinvestigated the chemistry of these potent plants. According to him at least three distinct species of water hemlock, growing in the United States along the banks of streams and in marshy ground, contain the same poisonous principle, which is located primarily in the rootstalk of the plant. Cicutoxin is an unstable resinlike substance of the formula $C_{10}H_{20}O_3$, and is a complex derivative of pyrone. It decomposes and polymerizes readily, especially at temperatures above 50 C. (122 F.). A reliable chemical test for its presence has been found. The lethal dose of this "spasmotoxin," which produces symptoms that include a paroxysmal and a paralytic stage, cannot yet be given with any approach to accuracy. The order of magnitude may be indicated by the fact that about 50 milligrams per kilogram of body weight will kill small animals. Death usually ensues from asphyxiation and exhaustion. No antidote is at present known. The allaying of the convulsive symptoms by means of a narcotic is at best a palliative procedure.

AN IMPORTANT RULING ON THE HARRISON LAW

Since the Harrison law went into force, frequent inquiries have been made as to the quantity of drugs which a physician was justified in prescribing or dispensing. Obviously, the quantity necessary in chronic cases or in the treatment of drug habitués differs materially from the quantity permissible in an ordinary case. The law makes no provision on this point, except to provide in general terms that, whether prescribing or dispensing, all acts coming under the scope of the law must be in good faith and not to evade the purposes of the act. It has been evident that some supplementary ruling on this point would be necessary. The Commissioner of Internal Revenue has just issued a ruling, dated May 11, which provides that

> "where a physician, dentist, or veterinarian prescribes any of the aforesaid drugs (those included in the provisions of the Harrison law) in a quantity more than is apparently necessary to meet the immediate needs of a patient in the ordinary case, or where it is for the treatment of an addict or habitué to effect a cure, or for a patient suffering from an incurable or chronic disease, such physician, dentist, or veterinary surgeon should indicate on the prescription the purpose for which the unusual quantity of the drug so prescribed is to be used. In cases of treatment of addicts, these prescriptions should show the good faith of the physician in the legitimate practice of his profession by a decreasing dosage or reduction of the quantity prescribed from time to time, while on the other hand in cases of chronic or incurable diseases, such prescriptions might show an ascending dosage or increased quantity. Registered dealers filling such prescriptions should assure themselves that the drugs are prescribed in good faith for the purpose indicated thereon, and if there is reason to suspect that the prescriptions are written for the purpose of evading the intentions of the law, such dealers should refuse to fill same."

Under this ruling, physicians must place on their prescriptions, whenever, for any reason, an unusual quantity of opium or cocain is prescribed, a statement of the reasons for such an order. If the physician and patient are acting in good faith, it is difficult to see any objection to such a provision. There will, of course, be some sensitiveness on the part of secret drug addicts to having their weaknesses made a matter of record, but this can hardly be avoided in any plan which will separate the genuine from the spurious demand for these drugs. The ruling of the Commissioner will clear up a point on which there has been much discussion. As The Journal has constantly stated, the object of the Harrison law is to secure publicity in the use of habit forming drugs and to effect the prosecution and punishment of all persons using them for illegitimate purposes. Compliance with this ruling will relieve physicians of responsibility and will make the prescribing or dispensing of unusual amounts of these drugs a matter of record.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Home for Incurables Opened.—A new home for incurables at the corner of Geary and Wood streets, San Francisco, was formally opened April 26. The building will accommodate thirty-six patients.

Vaccination Foes Defeated.—The senate, May 5, refused passage of the Gelder bill, which releases schoolchildren and students from compulsory vaccination. The bill was defeated by a vote of 23 to 12.

Hospital Dedicated.—On May 1 the new San Francisco City and County Hospital group of buildings on Protrero Avenue, erected at a cost of $2,000,000, was dedicated with appropriate ceremonies. The president of the board of works formally delivered the completed buildings to the mayor, who accepted the group in the name of the citizens of San Francisco. There are 350 beds at present ready for occupancy.

Physician's Tax Annulled.—The section of the local license ordinance of Turlock, which imposed a tax of $10 a day on transient physicians practicing in that city, was declared unconstitutional by Superior Judge L. W. Fulkerch, April 28, when he granted a petition for the release of Dr. J. H. Berry, on a writ of habeas corpus. The proceeding held that the section was "discriminatory, prohibitive and unreasonable."

Personal.—Dr. Samuel H. Horwitz has been appointed instructor in research medicine in the Hooper Foundation for Medical Research of the University of California, San Francisco.——Dr. Edouard C. Fabre-Rajotte, San Francisco, has been appointed eye, ear, nose and throat specialist to the French Hospital in that city.——Dr. Jacob H. Parsegan, San Francisco, has returned after a trip to Marsovan, Turkey, and Asia.——Dr. William A. Brooke, Halfmoon Bay, has been appointed coroner and public administrator of San Mateo County.

Hospital Notes.—The cornerstone of the Methodist Hospital of Southern California, Los Angeles, was laid May 3. The building is to be of reenforced concrete, six stories and basement in height, will accommodate 120 patients and will cost when completed, $210,000.——The Bellevue Hospital Corporation has been organized at Los Angeles, to erect a hospital to be known as the Bellevue Hospital, to contain about sixty rooms and to cost about $60,000.——The French Hospital Association has revived the plan to erect a modern hospital building at the corner of College and Castelar streets, Los Angeles. The building will cover a ground space of 150 by 40 feet, will be two stories in height and will contain two wards and eighteen private rooms, beside the necessary surgical rooms, kitchen and administrative offices, and the building is estimated to cost about $40,000.

FLORIDA

Florida has a Single Board.—A bill providing for a single board of medical examiners, in place of the three separate and independent boards, has passed the Florida legislature. The law also provides for a reregistration of all physicians and osteopaths in the state.

GEORGIA

War on Hookworm.—The board of commissioners of Randolph County has made a special appropriation of $150,000, to be spent in fighting hookworm in that county.

Drainage Expert to Fight Typhus.—Mr. George Hazelhurst, formerly of Atlanta, an expert engineer in drainage work of Savannah, has accepted a position under the Rockefeller Foundation for work against typhus fever in Serbia.

Personal.—Dr. Walpole C. Brewer, Atlanta, has started for New York for service with the British Red Cross.——Dr. G. H. Lowden, assistant superintendent, has succeeded Dr. Louis Hollander as superintendent of the Battle Hill Tuberculosis Sanatorium.——Dr. J. L. Adams was shot and seriously wounded near Donaldsonville, April 13.

Ware County in Advance.—A new epoch in public health work has begun with the action of the commissioners of Ware County in creating the office of county health officer. A health officer for each county in Georgia was authorized by the Ellis bill in the 1914 legislature, the authorization being subject to approval by the board of commissioners.

Health Officers Meet.—The Georgia Association of County and Municipal Health Officers met in Macon, April 20, and elected Dr. Howard J. Williams, Macon, president, and Dr. Peter J. Bahnsen, state veterinarian, secretary. A committee was appointed to memorialize the Georgia legislature to pass a law at its next session, requiring that each town and city in the state record vital statistics.

Sanatorium Wants New Buildings.—On the ground that the constantly increasing number of patients at the Georgia State Sanatorium, Milledgeville, renders imperative the provision of additional facilities, the trustees of that institution have recommended to the next general assembly an appropriation of $500,000, with which to erect and equip new buildings. The buildings for which there is most urgent need are new wards, one for white women and one for negroes, a hospital for the treatment of curable cases and a nurses' home.

State Medical Association Meeting.—The sixty-sixth annual meeting of the Medical Association of Georgia was held in Macon, April 21 to 23, under the presidency of Dr. William B. Hardman, Commerce. Columbus was selected as the next place of meeting and the following officers were elected: president, Dr. William S. Goldsmith, Atlanta; vice-presidents, Drs. Olin H. Weaver, Macon, and George B. Smith, Rome; secretary-treasurer, Dr. William C. Lyle, Augusta, reelected; councilors, tenth district, Dr. James A. Price, Milledgeville; eleventh district, Dr. Lee Howard, Waycross; twelfth district, Dr. Edward F. Coleman, Graymont; delegates to the American Medical Association, Drs. Mallie A. Clarke and Charles C. Harrold, Macon, and alternates, Drs. Wyman W. Pilcher, Warrenton, and Thomas J. McArthur, Cordele. The association adopted resolutions favoring Atlanta as the meeting place for the American Medical Association in 1916.

ILLINOIS

Leper Colony Planned.—The Illinois State Board of Administration has planned to establish a leprosarium in connection with the Alton State Hospital, which is now under construction.

Banquet to Interns.—The attending physicians of St. John's Hospital, Springfield, gave a dinner to the interns of the hospital at the St. Nicholas Hotel, April 29. Dr. Ben B. Griffith was toastmaster.

Municipal Health Officers Should be Physicians.—The Elgin Physicians Club, at its meeting May 3, adopted resolutions petitioning the mayor and commissioners to change the ordinance regarding the health department, so that the health officer must be a qualified physician with laboratory experience.

Personal.—Dr. Henry G. Wildman of the County Tuberculosis Hospital, Oak Forest, has been restored to professional standing by the decree of Assistant County Judge Hoover, dated May 14.——Dr. Walter Stevenson, Quincy, who has been ill with diphtheria, is convalescent and has resumed practice.——Dr. Henry S. Bennett has succeeded Dr. Perry H. Wessel as city physician of Moline.

Epidemic Diseases.—On account of the prevalence of scarlet fever at Mattoon, orders have been issued that no child under 16 may attend moving-picture shows or other public gatherings.——Measles is very generally prevalent in Jacksonville. The epidemic is mild in its type.——The health officer of Rock Island reports that during the month of April, 154 cases of measles and 20 cases of smallpox were reported in the city.——Schools at Ashton have been closed and public meetings interdicted on account of an epidemic of smallpox.——Smallpox of a mild type is reported from Rochelle.——During April, 109 families in Pana were under quarantine for measles and 13 families on account of smallpox.

Chicago

Child Welfare Taken up by Society.—The May 5 meeting of the Chicago Medical Society was devoted entirely to the subject of child welfare.

Appeal for Funds.—The Chicago Tuberculosis Institute appeals for contributions to make up the deficit of about $2,500 of the $12,000 needed for the budget for the year.

Rosenow Joins Mayo Foundation.—Dr. E. C. Rosenow, a member of the staff of the Memorial Institute for Infectious Diseases, has been appointed one of the directors of the Mayo Foundation and chief of the department of bacteriologic research. He expects to assume his new duties about July 1.

Personal.—Dr. Robert L. I. Smith sailed for Europe, May 8, to work in the Belgian Red Cross with Dr. Dupage, surgeon-general of the Belgian army.——Dr. Anna Dwyer has been appointed a member of the subcommittee of the morals commission on regulation of pool rooms and additional recreation facilities.

Public Laundry Suggested.—The commissioner of health has suggested to the mayor the establishment of a public laundry in connection with the public municipal bath to be built on North Lincoln Street near Augusta. In this plan Chicago is years behind the cities of Europe and especially England, which has had for many years public laundry facilities in connection with the public baths.

KANSAS

New Hospital.—George M. Hoffman, a banker of Rice County, is about to establish a hospital in Little River, to be under the charge of Drs. L. H. Powers and Louie J. Beyer, Little River.

Personal.—Dr. Rollo C. Dugan, Ottawa, superintendent of the Ottawa Hospital, who has been under treatment in Chicago, has returned and resumed practice.——Dr. George H. Hobson, Kansas City, has temporarily succeeded Dr. Chilton W. McLaughlin as health officer of Kansas City.

University Health School.—A free course of instruction for Kansas physicians was given in the Bell Memorial Building, Rosedale, by the University of Kansas and the State Board of Health for two weeks, from April 26 to May 10. Among other speakers, Dr. John S. Fulton, secretary of the Maryland State Board of Health, delivered an address on "Population and Birth"; Surgeon Mark J. White, U. S. P. H. S., St. Louis, discussed "The Pathology and Diagnosis of Bubonic Plague," and Dr. Albert J. Chesley, Minneapolis, director of the division of preventable diseases of the Minnesota State Board of Health considered the "Organization of the State Public Health Service."

Protests Quarantine.—At a meeting of the State Livestock Sanitary Board held in Lincoln, Neb., April 23, an emphatic protest was made by the state of Kansas against the quarantine which Nebraska has enforced against Kansas livestock as a precaution against the foot and mouth disease. During the past six months, Kansas has had six outbreaks of this disease, and it has been necessary to kill 1,217 cattle valued at $72,588.78 and 313 hogs valued at $3,463.20. The owners of the animals were reimbursed in full by the state and national governments. In addition to this, the state has paid $38,025.99 for disinfection and in addition, the necessary veterinary inspection.——Notice has been served on the Texas livestock commission by the state of Kansas that quarantine will be declared against Texas unless that state lifts the ban against Kansas.

State Society Meeting.—The Kansas Medical Society held its forty-ninth annual meeting in the Masonic Temple, Kansas City, Kan., May 5 and 6, under the presidency of Dr. William F. Sawhill, Concordia, and elected the following officers: president, Dr. Oliver D. Walker, Salina; vice-presidents, Drs. Charles W. Jones, Olathe; Benjamin F. Chilcott, Osborne, and John R. Scott, Newton; secretary, Dr. Charles S. Huffman, Columbus (reelected); treasurer, Dr. Lewis H. Munn, Topeka (reelected); councilors, first district, Dr. Charles W. Reynolds, Holton; second district, Dr. Clarence C. Goddard, Leavenworth; seventh district, Dr. Kirk P. Mason, Concordia; eighth district, Dr. Howard N. Moses, Salina, and ninth district, Dr. Chauncey S. Kenney, Norton; delegate to the American Medical Association, Dr. William F. Sawhill, Concordia. Topeka was selected as the next place of meeting.

MARYLAND

Sanitary Engineer Starts for Serbia.—Charles E. Fox of the State Sanitary Engineering Department sailed for Serbia, May 13, to serve as sanitary inspector under the Serbian government. His special duty will be the cleaning up of the typhus plague spots in Serbia.

To Build New Hospital.—Tentative plans looking to the abandonment of its present building and the erection of a modern new hospital in North Baltimore are being considered by the board of trustees of the Union Protestant Infirmary, who are negotiating for a site near Homewood.

Brady Institute Opened.—The formal opening of the James Buchanan Brady Urological Institute, Johns Hopkins Hospital, took place on May 4 with elaborate exercises. There were formal dedicatory exercises early in the afternoon, followed by a reception to Mr. Brady, and in the evening a banquet was held at the Belvedere Hotel. Among those making addresses at the opening were: Dr. Hugh H. Young, Director of the Institute, Dr. William H. Welch and Dr. Edward L. Keyes, of New York.

Physicians Officiate at Church Service.—On May 16, the services at the Emmanuel Protestant Episcopal Church, Baltimore, were participated in by a number of practitioners in attendance on the meeting of the Medical and Chirurgical Faculty of Maryland. Dr. Richard Clarke Cabot, Boston, delivered the sermon, the lessons were read by Drs. Winford H. Smith and Hiram Woods, and the ushers were Drs. Frank Martin, William W. Russell, John M. Hundley and Page Edmunds.

Gift for Johns Hopkins Hospital.—Dr. Winford H. Smith, superintendent of the Johns Hopkins Hospital, has announced a gift of $16,500, to be paid in three yearly instalments, from John D. Rockefeller, Jr., to be used in a special social hygiene department at the hospital, which is to be established next September. The work of the new clinic will be in charge of a committee consisting of Dr. George H. Walker, chairman, Dr. Theodore C. Janeway and Dr. Winford H. Smith. Dr. Albert Keidel, a graduate of the Johns Hopkins Medical School, will be the physician in charge of the new dispensary. He will have four assistants.

Personal.—Dr. David K. Henderson, Baltimore, has resigned as resident physician to the Phipps Psychiatric Clinic, Baltimore, to accept a position as superintendent of the Glasgow Royal Asylum, Scotland.——Dr. Roscoe W. Hall, Baltimore, who is assistant resident physician at the Phipps Clinic, has been appointed by Dr. Winford H. Smith to fill the vacancy caused by the resignation of Dr. Henderson. Dr. Charles B. Thompson has been made first assistant physician and Dr. Augusta Ruby Scott, second resident. Dr. Scott is the first woman to hold this position.——Dr. Walter L. Nicholls, Baltimore, recently underwent operation at the Mercy Hospital.——Dr. John C. Travers, of Baltimore, has been appointed by Health Commissioner Nathan R. Gorter, assistant physician at the Quarantine Hospital to succeed the late Dr. E. G. Altvater.——Dr. John J. Szymanki Schmitt, a young Polish physician, who is at present engaged in special urological work at the Johns Hopkins Hospital under Dr. Hugh H. Young, sailed May 13 from New York for Piraeus, Greece, where he will act in the capacity of sanitary inspector in conjunction with the American Red Cross work.——Dr. Robert H. Crawford, an intern at the Union Protestant Infirmary, has sailed for Europe to engage in Red Cross work. He will land at Rotterdam and go from there to Germany.——Dr. John E. Fisher, Baltimore, was thrown from his buggy in a collision with a motorcycle, May 5, and was painfully injured.

State Medical Faculty Elect.—At the one hundred and seventeenth annual meeting of the Medical and Chirurgical Faculty of Maryland held in Baltimore, April 27 to 29, the following officers were elected: president, Dr. J. Whitridge Williams, Baltimore; vice-presidents, Drs. Lewis C. Carrico, Bryantown; Milton D. Norris, Eldersburg; and Joseph A. Chatard, Baltimore; secretary, Dr. Joseph I. France, Baltimore; treasurer, Dr. William S. Gardner, Baltimore; delegate to the American Medical Association, Dr. G. Lane Taneyhill, Baltimore; alternate, Dr. Herbert Harlan, Baltimore; councilors, Drs. Guy Steele, Cambridge; J. B. Johnson, Frederick; Henry L. Naylor, Pikesville; William J. Todd, Mount Washington, and Edwin B. Claybrook, Cumberland; and Drs. David Streett, Wilmer Brinton, Randolph Winslow and Harvey B. Stone, Baltimore; members of the State Board of Medical Examiners, Drs. John L. Riley, Snow Hill; and Lewis A. Griffith, Upper Marlboro (reelected). A large oil portrait of the late Dr. William Travis Howard, professor of diseases of women in the University of Maryland from 1867 to 1897, and presented to the faculty by Dr. Howard's widow, was unveiled in Osler Hall, Baltimore, April 27. Dr. J. Whitridge Williams made the speech of presentation and the portrait was accepted in behalf of the faculty, by Dr. J. W. Humrichouse. Two amendments to the constitution were adopted, one abolishing the Board of Trustees and the other, increasing the members of the council from eleven to fifteen.

MISSISSIPPI

State Association Meeting.—The Mississippi State Medical Association held its annual meeting in Hattiesburg, May 11 to 13, and elected the following officers: president, Dr. Inman W. Cooper, Newton; vice-presidents, Drs. Walter H. Scudder, Mayersville; William L. Orr, Fulton, and James W. Lucas, Moorhead; councilors, third district, Dr. Charles M. Murry, Ripley; fourth district, Dr. Felix J. Underwood, Nettleton; ninth district, Dr. John C. McNair, Fayette; delegate to the American Medical Association, Dr. Jacob S. Ullman, Natchez; alternate, to be appointed by the president-elect; members of the State Board of Health, Drs. S. Wade Glass, Lyon; Samuel E. Eason, New Albany; Thomas F. Elkin, Tupelo; Thomas H. Seay, Laurel, and John H. Johnson, Brookhaven. It was voted to continue the present arrangement with the *Pan-American Medical and Surgical Journal*.

NEBRASKA

State to Make Sanitary Survey.—A proposal to make an extensive and thorough sanitary survey of the state has been made by the board of secretaries of the State Board of Health on a plan similar to that pursued by Dr. Oscar Dowling in Louisiana.

Personal.—A farewell dinner was given, May 6, to Dr. Anders P. Overgaard by the Dodge County Medical Association at Fremont. Dr. Overgaard expects to reside in Omaha.——Dr. Arthur A. Spoor, Omaha, of the University of Nebraska, has been appointed state bacteriologist of Michigan.

Smallpox.—Seven new cases of smallpox were reported to the health office at Hastings, April 21. This makes a total of 36 cases since the epidemic began. Those who neglect to report cases are to be vigorously prosecuted.——The smallpox situation at Benkelman is now considered to be well under hand. Only one or two new cases developed during the last week.

Hospital News.—An architect has been selected for the state hospital building, to be erected on the campus of the College of Medicine of the University of Nebraska, Omaha. The building with equipment will cost about $50,000. It will be in the same general style of architecture as the college building and will be erected west and a little south of the latter.

NEW YORK

Appropriations for Port Health Office.—Dr. Joseph H. O'Connell, Health Officer of the Port of New York, after a hearing before Governor Whitman, secured the appropriations he had requested.

Payments for Birth and Death Records.—As the result of the enactment of an amendment to the health law which has been recently signed by the governor, physicians will receive a fee of twenty-five cents for each birth and death record filed. This, it is hoped, will do away with the difficulties which have heretofore arisen from non-registration or improper or late registration of births and deaths.

Amend Habit-Forming Drug Law.—The Boylan law has been amended so as to make it unnecessary to use the "Boylan Law" order blanks in order to secure these drugs, provided that the State Commissioner of Health approves in their place such order blanks as may be issued under an Act of Congress. The Commissioner of Health has approved the order blanks required by the federal (Harrison) law and it will therefore in the future be unnecessary to use the Boylan law blanks if the federal order blanks are used.

Contagious Diseases.—It is reported from Poughkeepsie that the scarlet fever situation is well in hand and that no case has developed among the pupils of the public schools beyond the thirteen reported.——The epidemic of measles in Syracuse is said to be on the increase. During April, 528 cases were quarantined and there were 225 under quarantine on May 6.——The foot and mouth disease quarantine in the townships of North Greenbush, East Greenbush, Sand Lake, Poestenkill, Grafton, Pittstown, and Schaghticoke, has been ordered to be raised except within a radius of three miles of any farm or on farms where foot and mouth disease has actually existed.——Fourteen families in the north end of Olean are under quarantine for smallpox. The public school has been closed and a general order has been issued for the vaccination of the school children.

Personal.—Dr. James T. Houghton, Saratoga Springs, a passenger on the *Lusitania* on her last trip, is on his way to take his place on the surgical staff of the Belgian Red

Cross.——Dr. Edgar A. Vander Veer has been elected president and Dr. George E. Gorham, secretary, of the Bender Hygienic Laboratory, Albany.——Dr. Henry Hun has been elected a member of the Board of Trustees. At the last meeting of the board, the resignations of Drs. Albert Vander Veer and Willis G. Tucker were accepted and votes of thanks were given to them for their labors.——Dr. O. W. H. Mitchell, has resigned as city bacteriologist of Syracuse to accept the chair of bacteriology in the College of Medicine of the University of Syracuse.——Dr. Mason R. Pratt, Syracuse, has assumed his new duties as superintendent of the Hebrew Hospital, Baltimore.——Dr. James E. Burns, Glen Cove, L. I., has been appointed inspector for the Long Island District under the new Harrison law.

New York City

Clinic Moves.—The municipal clinic for diseases of the throat and lungs has been moved to a building secured by the Board of Health at 420 Herkimer Street, Brooklyn.

Personal.—Dr. F. Warren Pearl of New York City was among those rescued from the *Lusitania*.——Dr. and Mrs. Henry H. M. Lyle arrived from Liverpool on May 13.

Smallpox on Arriving Ship.—The steamship *Havana*, which arrived from Havana, May 12, had aboard a case of smallpox. All the other passengers were ordered to be vaccinated before being allowed to land.

Division of Statistical Research.—A division of statistical research will be organized within the Bureau of Records on Jan. 1, 1916. An effort will be made to utilize the activities of this new department in such a way that other bureaus of the Department will be guided in their work by its findings. Such a division has been repeatedly recommended by special committees.

Dr. Goldwater Offers to Run Street Railway.—Health Commissioner Sigismund S. Goldwater, while admitting that he is going outside the bounds of his department, has published an unofficial offer made to Theodore P. Shonts, President of the New York Railways Company, to operate the cars on the Sixth Avenue line for an experimental period, as he is thoroughly convinced that at least 10 per cent. more cars could be run than at present.

Health Department Undertakes Novel Investigation.—The Department of Health has organized an experimental health district for the purpose of making a trial of the merits of local or decentralized municipal health administration. The activities of the department in "Health District No. 1" will continue to be identical with those of the department elsewhere. This plan is to be continued except that advantage will be taken of every means of increasing the effectiveness of the work by cooperation with local civic agencies and by arousing and sustaining in the district's residents an interest in personal hygiene. To this end an exhaustive study is being made of housing, occupation, recreation, and the habits and resources of the entire population, with the object of thus developing rationally a health program which will deal in an effective way with whatever is found actually to impede healthful living. All physicians and others interested in health matters are invited to visit the Headquarters of Health District No. 1 at 206 Madison Street.

Labor Health Bureau Started.—The Commissioner of Health, Dr. Sigismund S. Goldwater, has directed the formation of a new division of the Bureau of Infectious Diseases, to be known as the division of industrial hygiene, and of this, Dr. Lewis L. Harris has been designated chief. The tentative program of the work of this division includes:

> "1. A general 'industrial survey' comprising (a) a statement of the number of employes in the city in extra hazardous occupations, and (b) a general statement as to where the most unhygienic 'plants' under these industries are situated.
>
> "2. An intensive study of the conditions of work and the physical condition of the workers in, say, half a dozen of the most hazardous industries in the city.
>
> "3. Arrangements with certain dispensaries to open special occupational disease clinics to which all sufferers from occupational ills could be referred.
>
> "4. All observations should be checked with corresponding data as to home conditions, else conclusions may be assailed as incomplete. For example, tuberculosis among garment workers may be wholly due to home conditions and the workshop may be exceptionally hygienic. This could, in part, be done by co-operation with the Tenement House Department, although social service workers are the proper persons to obtain such data."

Summary of Health Activities of Academy.—The Public Health Committee of the New York Academy of Medicine has published in leaflet form, a summary of its activities for March and April, which include a medical estimate of certified milk; an amendment to the penal law relating to necropsies; an inquiry into the practicability and feasibility of so changing the present law as to require a year of hospital training for all applicants to practice medicine; a questionnaire as to the number of cases of heart disease in children cared for in hospital wards and dispensaries; the problem of providing adequate facilities for the treatment of drug habitués; the medical and sanitary care of inmates of the Home for the Aged; the conditions existing at the hospital of the Workhouse on Blackwell's Island and the need of improving the medical service; cooperation in the meeting on quarantine held April 20; consideration of many of the bills relating to public health and the strong opposition to the so-called Hinman bills and also the bill exempting Christian Science practitioners from the provisions of the medical practice act.

Limitations of the Dairy Score Card.—A bulletin recently published by the New York Agricultural Experiment Station at Geneva sets forth in detail an interesting series of experiments as to the relationship of dairy scores and bacteria values of certain milk supplies. These experiments were conducted by Dr. Brew and seem to show that a dairy score card does not furnish a reliable index to the quality of the milk, inasmuch as it is found that in many instances the best milk from a bacteriologic point of view came from low score dairies, while milk from high score dairies was found grossly contaminated. One of the most important conclusions arrived at was that one shortcoming of the score card was its inability to take account of the personal equation of the dairyman himself. A clean dairyman will produce a clean article even under adverse conditions, whereas a dirty individual would produce dirty milk even under the best conditions. It seemed, however, that where such a degree of care was given as was required by the numerous details noted on the score card it was safe to assume that due precaution was taken to safeguard against accidental pollution that was not guarded against on the average low score dairy farm. The finding that only two of the dairies used ice made it probable that insufficient cooling had something to do in creating the conditions reported.

Educational Lunch Room Opened.—The New York Department of Health, on May 10, opened an educational lunch room for its employees at the headquarters of the department. The enterprise is being financed by the employees themselves. At the opening of the lunch room there were present the Acting Mayor Hon. George McAneny, Borough President Marcus M. Marks, Professor Graham Lusk, and many other distinguished guests. The menu issued daily lists under the heading of "Specials" the item sold, the price, quantity, number of calories and grams of protein. Two specimen lunches furnishing a balanced ration at low cost and at high cost—22c and 46c—respectively are offered. Under the heading "Ready Every Day" items are again listed with price, quantity, number of calories and grams of protein. The back of the menu is given over to many hints with the heading "Food Wisdom." Examples are:

> Clerks, stenographers and the average adults doing office work need about 2,500 calories a day. Mechanics and artisans need about 3,000 to 3,500 calories per day, while laborers, longshoremen and others doing hard work need 3,500 to 4,500 calories per day.
>
> Your lunch should consist of sufficient food to supply about 1,000 calories; 90 per cent. of these should be in the form of starches and fats. Look at the specimen lunches on this bill of fare and notice that this can be obtained for various prices.
>
> Food should have not only sufficient nourishment, but should also supply certain necessary constituents to rebuild body tissue. Chief among these are protein and mineral salts.
>
> Protein is especially abundant in meat, eggs, fish, milk, cheese, beans and peas.

NORTH CAROLINA

Ground Broken for Hospital.—Ground was broken April 22, for the new Mercy General Hospital, to be built east of Charlotte.

Drug Law Conviction.—T. L. Love, a colored druggist of Raleigh, is said to have been convicted and fined $300 for violation of the state statute.

Investigates Prison Camps.—By direction of the governor, Dr. Watson S. Rankin, Raleigh, secretary of the State Board of Health, is making an investigation into the sanitary condition of the various prison camps in the state.

State Society to Meet.—The annual meeting of the Medical Society of the State of North Carolina will be held in Greensboro, June 15 to 17. On June 14 the State Health Officers Association will hold its annual session.

Sanitary Survey Started.—A sanitary survey of Orange County, which is being made by the United States Public Health Service and the North Carolina State Board of Health, was started by Surgeon Leslie L. Lumsden, U. S. P. H. S., this month. He is being assisted by Dr. E. C. Branson of the state university.

Personal.—Dr. George M. Cooper, Clinton, whole-time health officer of Sampson County, began work May 10, as chief of the bureau of rural sanitation and as assistant secretary of the State Board of Health.——The house of Dr. Garrett D. Gardner, West Asheville, was destroyed by fire, April 22, with a loss of $4,000.——Dr. John A. Williams, Greensboro, while visiting New York City was seized with a cerebral hemorrhage and taken to the Hudson Street Hospital. He is reported to be improving.——Dr. James D. Cochran, Fayetteville, has returned after a long stay in New York City and will remove to Nashville, Tenn.——Dr. H. D. Taylor, professor of bacteriology and pathology in the Wake Forest Medical School, has resigned to accept service with the Rockefeller Institute for Medical Research, New York City.——Dr. Owen H. Kenan, Wilmington, was one of the rescued passengers of the *Lusitania*. He was on his way abroad to engage in the Red Cross service. He was ill for several days, but is now reported to be convalescent.——Dr. Henry M. Tucker, Raleigh, has returned after several months postgraduate work and resumed practice.——Dr. George R. Cooper has been placed in charge of the newly created bureau of rural sanitation and just opened his office in the building occupied by the State Board of Health, Raleigh.——Dr. John W. P. Smithwick has been elected mayor of La Grange.——Dr. George W. Elias, Biltmore, and Dr. Montgomery H. Biggs, Rutherfordton, have been elected aldermen.——Dr. Raymond A. Pollock, New Bern, has returned after a course of postgraduate study in New York City.——Dr. Jesse M. Russell, Canton, has been commissioned lieutenant in the Medical Corps, North Carolina National Guard and assigned to duty with the Canton Ambulance Company, succeeding Dr. J. Rufus McCracken, Waynesville, resigned.——Dr. Michael P. Cummings has been elected mayor of Reidsville.

OHIO

Society to Study Alcohol.—The Ohio Society for the Study of Alcohol and Other Narcotics, was organized in Cincinnati May 6; Dr. Simon P. Kramer was elected chairman pro tem. The society has a charter membership of 23.

Physicians Organize.—The Cuyahoga Falls Medical Association was recently organized with the following officers: honorary president, Dr. Wayland C. Hough; president, Dr. John W. Caines, vice-president, Dr. Floyd D. Smith; secretary, Dr. Daniel C. Keller, Jr., and treasurer, Dr. Bayard T. Keller, Hudson.

Health Officials Must Not Interfere with Attending Physicians.—Under the new rules governing the work of the epidemiologist, communicable disease nurses and sanitary inspectors of the state will be given instructions that they are under no circumstances to "interfere with or criticize the treatment or diagnosis of the attending physicians."

Personal.—Dr. Mark D. Stevenson, Akron, is seriously ill in the People's Hospital, Akron, on account of an infected wound of the finger.——Dr. Morton W. Bland, state registrar of vital statistics, Bellevue, who has been critically ill, is reported to be improving.——Dr. Ben R. McClellan, Xenia, has been appointed a member of the state medical board, succeeding Dr. Augustus Ravogli, Cincinnati.——Dr. Cyrus W. Chidester, Delaware, has been re-elected great medical examiner of Ohio, by the state convention of Maccabees.

Communicable Diseases.—Quarantine against foot and mouth disease epidemic has been extended to the counties of Ashland, Medina, Mahoning, Lorain, Erie and Huron and also portions of Paulding, Miami and Montgomery counties.——Forty-one new cases of measles were reported in Cleveland May 4, bringing the total for four weeks to 719.——It is announced by the Youngstown Board of Health that the smallpox situation is now under control. At this time there were 18 cases under quarantine in 8 different houses. The health officer of Youngsville has been authorized to prepare the temporary detention hospital for use of the smallpox patients.——There are said to be nine cases of smallpox in the House of the Good Shepherd, Columbus, and sixteen cases have altogether been reported in the city.——In the Village of Berea and Middleburg township, fifteen cases of smallpox have been discovered.

State Society Meeting.—The annual meeting of the Ohio State Medical Association was held at the Hotel Gibson, Cincinnati, May 4, 5 and 6, and the following officers were elected: president elect and vice-president, Dr. Harmon B. Gibbon, Tiffin; president, Dr. William E. Lower, Cleveland; chairman of the committee on public policy and legislation, Dr. John H. J. Upham, Columbus; secretary-treasurer, and managing editor of the *Ohio State Medical Journal*, Dr. Clarence D. Selby, Toledo, and councilors—first district, Dr. Robert Carothers, Cincinnati; second district, Dr. John E. Hunter, Greenville; third district, Dr. Dana O. Weeks, Marion; fourth district, Dr. Charles W. Moots, Toledo; fifth district, Dr. Clyde E. Ford, Cleveland; sixth district, Dr. Edgar J. March, Canton; seventh district, Dr. James S. McClellan, Bellaire; eighth district, Dr. William E. Wright, Newark; ninth district, Dr. Joseph S. Rairdin, Portsmouth; and tenth district, Dr. Wells Teachnor, Columbus. Dr. George Dock, of Washington University, St. Louis, delivered the oration on medicine, the subject being, "The Thymus Gland," and Dr. Charles L. Scudder, Boston, gave the oration on surgery on "The Operative Treatment of Fracture of the Bone." Cleveland was selected as the next place of meeting.

PENNSYLVANIA

Vivisection Bill Recommitted.—"Dog Pound Bill," which would work for the promotion of animal vivisection was recommitted on third reading in the senate, May 10. This bill provides for the sale, distribution and use, for the promotion of biologic science, of unclaimed animals in public pounds, the sale figure to be $1.

New Bill for Optometry Board.—As a consequence of a meeting held in the office of the attorney-general, May 13, a bill may be passed in the last hours of the legislature establishing a state board for the examination and licensing of optometrists. Earlier in the session a bill was passed and vetoed. The governor objected on the ground that the bill limited appointments on the proposed board to persons selected by the Pennsylvania Optical Society, and that there was no reason why the optometrists could not place themselves under the existing state Bureau of Medical Education and Licensure.——Another bill providing for the appointment of an optometric examining board, now in the house, was the subject of conference. A tentative agreement was reached, it was said, that the measure should be amended so as to provide for the appointment of a board consisting of three physicians, three optometrists and the state superintendent of public instruction, and that the actions of this board should be subject to the approval of the State Board of Medical Education and Licensure.

Philadelphia

Personal.—Dr. Hobart A. Hare, who has been ill with pneumonia, has fully recovered and has resumed his practice and hospital work.——Dr. Willy Meyer of New York addressed the Philadelphia Clinical Association on May 17, and after the meeting was the guest of honor at a reception held at the Mercantile Club.

New Hospital for Babies.—A gift of 8½ acres of ground and several buildings on Manoa Avenue near Llanerch, Delaware County, has been made to the Babies' Hospital of Philadelphia, by a friend whose name has not been disclosed. The property has been altered to care for the hundreds of babies under 3 years old, suffering with "summer complaint." For four summers the hospital has used the buildings of the Children's Hospital at Wynnfield.

Penny Lunches in Schools.—Beginning next September the pupils in twenty-five elementary schools in South Philadelphia will be able to buy penny lunches at the morning recess. The superintendent of schools has been authorized to equip each building with luncheon counters. The home and school league for eight years has carried on luncheon rooms in nine schools, feeding 5,800 children.——A sample menu for the luncheons is as follows: One cent lunch—cocoa, graham wafers, milk, three pretzels, five stewed prunes, bean soup, rice pudding, sweet chocolate. Three cent lunch—bean soup, bread, stewed peaches or ham sandwich, cocoa, graham wafers, or hamburg steak in gravy, rice, bread.

Paris Hospital Staff Named.—Announcement has been made by Dr. J. William White of the personnel of the group of surgeons who will assume charge of the American Ambulance Hospital in Paris for the months of July, August and September, succeeding the Harvard group which has been in charge since April 1. Dr. James P. Hutchison will be managing head. The expedition is to be financed by voluntary contributions. About $10,000 is needed of which $5,000 has already been received. The physicians will pay their own expenses and serve without salary. The members of the group are, surgeon, Dr. James P. Hutchison, adjunct professor of surgery of the University of Pennsylvania; neurologist, Dr. Daniel J. McCarthy, professor of medical jurisprudence in the university; assistant surgeon, Dr. Edmund B. Piper, former chief resident surgeon of the University Hospital; Dr. Walter E. Lee, assistant surgeon at the Bryn Mawr and Germantown hospitals; Dr. Arthur E. Bitting, assistant surgeon, Pennsylvania Hospital; Dr. Peter Mc. Keating, Wawa, assistant attending surgeon at Bryn Mawr Hospital; bacteriologist, Dr. Samuel Goldschmidt Girrin, fellow in research medicine, University of Pennsylvania.

TEXAS

Malta Fever at Uvalde.—Five members of a family who were brought to Uvalde for treatment, April 30, have been found to be suffering from malta fever.

Tuberculosis Cottages Open.—The eight new tuberculosis cottages at the Fort Worth County Poor Farm were opened for occupancy, May 1. The city of Fort Worth has agreed to pay one half the expenses connected with the care of the patients.

New Officers for County Secretaries.—The Association of Secretaries for County Medical Societies of Texas held its annual meeting in Fort Worth, May 6, and elected Dr. James C. Loggins, Ennis, president; Drs. Bacon Saunders, Fort Worth, and Frank Paschal, San Antonio, vice-presidents; and Dr. Holman Taylor, Fort Worth, secretary, ex officio.

Hospital to Open.—Physicians of Oak Cliff met April 23, and formed the Oak Cliff Medical and Hospital Association for the purpose ultimately of securing the establishment of a hospital in the Oak Cliff section of Dallas. Dr. Bert E. Greer was elected president; Dr. Albert Wilkinson, vice-president, and Dr. Homer Donald, secretary of the association.

Northwest Texas Physicians Meet.—At the annual meeting of the Northwest Texas Medical Association held in Wichita Falls, April 13 and 14, the following officers were elected: president, Dr. James H. Eastland, Mineral Wells; vice-president, Dr. Claud F. Young, Bowie, and secretary, Dr. Robert A. Duncan, Graham. Mineral Wells was chosen as the next place of meeting.

Plea for County Hospitals.—Dr. William B. Collins, Lovelady, state health officer, has issued a statement calling attention to the importance of establishing county hospitals in the various counties of the state, and especially for those suffering from communicable diseases. The county hospital law, passed by the legislature in 1913, which permits any county to construct a hospital for the care of its sick, has been employed by only six counties up to date.

Personal.—Dr. John S. Cooper, Dallas, sailed for Liverpool, May 1, as surgeon on the Booth Line steamship *Alden.*——Dr. John C. Cassity, San Antonio, was shot and painfully wounded in an affray at Eminence, Ky., May 5.——Dr. James M. Nicks, Ranger, fell in Fort Worth, May 4, fracturing his left forearm.——Dr. D. Clinton Burkes, Belton, has entered on his duties as assistant in the Southwestern Hospital for the Insane, San Antonio.——Dr. Albert G. Clopton, Jefferson, is reported to be critically ill with pneumonia, at the home of his son in Washington, D. C.

State Association Meeting.—At the forty-ninth annual meeting of the State Medical Association of Texas, held in Fort Worth, May 4, 5 and 6, the following officers were elected: president-elect, Dr. James M. Inge, Denton; president, Dr. George H. Moody, San Antonio; vice-presidents, Drs. Murff F. Bledsoe, Port Arthur; Hardy C. Black, Waco, and Thomas D. Frizzell, Quanah; trustee, Dr. William R. Thompson, Fort Worth; councilors, first district, Dr. Felix P. Miller, El Paso; fourth district, Dr. Stoyell C. Parsons, San Angelo; twelfth district, Dr. Cleve C. Nash, Palestine; thirteenth district, Dr. Charles B. Williams, Mineral Wells, and fourteenth district, Dr. Alva W. Carnes, Hutchins; delegates to the American Medical Association, Drs. Andrew B. Small, Dallas; Holman Taylor, Fort Worth, and Manton M. Carrick, Dallas; and alternates, Drs. Frank Paschal, San Antonio; Edward H. Cary, Dallas, and John H. Foster, Houston. Galveston was selected as the next place of meeting.

German-American Doctors Prosecuted.—In the United States court at Houston early in April six men practicing as the German-American Doctors in Houston and two stenographers were convicted of using the mails to defraud and were sentenced to the United States prison at Leavenworth for various terms varying from three years to a year and a day. Among those convicted were Nathan and T. W. Hughes, Walter P. Pegram, A. S. Olsen and O. F. Bourque. The defendants were placed in the Houston jail. Drs. N. A. and T. W. Hughes, April 3, furnished bail in the sums of $3,000 and $2,000, respectively, and were released. A writ of error was allowed in the federal court at New Orleans on the application of the parties named, but all of the defendants except N. A. and T. W. Hughes were unable to furnish bond and remained in jail. At the trial it is said it was brought out that the defendants caused to be mailed typewritten letters exactly alike to all who made out and sent in diagnosis blanks, no matter what their symptoms might be. The treatment was said to be the same in each case, the "medicine" being mixed by a negro porter in the offices of the German-American Doctors, who testified to this fact, it is said. The case against the doctors was worked up by U. S. government secret agents.

WISCONSIN

Smallpox.—Eight cases of smallpox in one family were discovered in Castle Rock, April 30.——An order compelling the vaccination of all Madison schoolchildren was issued by the Madison Board of Health, April 30, on account of the existence of 14 cases of smallpox in that city.

Wisconsin Surgeons Meet.—At the annual meeting of the Wisconsin Surgical Association held in Milwaukee May 5 and 6, the following officers were elected: president, Dr. F. Gregory Connell, Oshkosh; vice-presidents, Drs. Alfred H. Levings, Milwaukee; John M. Dodd, Ashland; Karl W. Doege, Marshfield; and Dennis J. Hayes, Milwaukee; secretary-treasurer, Dr. Daniel Hopkinson, Milwaukee; and regents, Drs. William C. F. Witte and Alfred H. Levings, Milwaukee. During the session of the association, clinics were held at the various hospitals of the city.

Personal.—Dr. Fern A. Rice, Delavan, is reported to be seriously ill as the result of hemorrhage of the stomach.——Dr. Leo J. Dretzka, Milwaukee, has been appointed superintendent of the new Detroit City Hospital.——Dr. Jesse Y. Potter, New London, who was operated on in Appleton, in March, has returned home convalescent.——Dr. Henry A. Pfeiffer, Jackson, sustained severe injuries by being thrown from his automobile near Jackson, Wis., April 21.——Dr. John R. Currens has been elected for the third term, mayor of Two Rivers.——Dr. Edward C. Fish, Mosinee, is reported to be seriously ill.

News About Hospitals.—Sunnyview, the new Winnebago County Tuberculosis Sanatorium which is being erected near Oshkosh, at a cost of about $30,000, is nearing completion. ——A stock company has been formed at Wausau to build a forty-room hospital, to cost $75,000.——Contracts for the Deaconess Hospital, Green Bay, have been awarded to the Appleton Construction Company. The building will cost $65,000.——Bids have been invited for the construction of a third wing to the Milwaukee Isolation Hospital on Mitchell Street. The building is to cost $100,000. It will have two departments, one for diphtheria and one for smallpox. The diphtheria ward will accommodate from 45 to 90 patients and the smallpox ward, from 55 to 110 patients.

GENERAL

Harvard Alumni at San Francisco.—At the coming meeting of the American Medical Association in San Francisco there will be a table d'hote luncheon at the University Club, the date to be announced later, for members of the Harvard Medical Alumni Association. Dr. William P. Lucas of the University of California, San Francisco, is in charge of the arrangements.

Gorgas Prize Medal.—Referring to the Gorgas Prize Medal, to be awarded yearly by the Association of the Medical Reserve Corps, U. S. Army, New York State Division, the Board of Award announces that the competition is open to officers of medical corps of the Army, of the Medical Reserve Corps of the Army and of the Organized Militia. The medal will be awarded for the paper submitted which shows the most important advance in medicine or surgery on a medical or medico-military subject; preference being given to papers on a medico-military subject. The Board of Award consists of three members of the Faculty of the Army Medical School, appointed by the Surgeon General. All papers should be submitted by March 31 of each year, and should be addressed to the President of the Board of Award, Gorgas Prize Medal, Army Medical School, Washington, D. C. The award will be announced at the graduation exercises of the Army Medical School, on May 31 of each year.

FOREIGN

Adoption of Age Limit for University Professors.—A bill is now pending in the Italian legislature, after favorable report by a committee, decreeing an age limit without any exceptions for all the professors in the universities throughout Italy.

The Campaign Against Alcohol.—The authorities at Milan are planning the organization of eight anti-alcohol drinking places as a further step in the systematic campaign against alcohol. It is proposed to grant to private parties the concession for operating these municipal alcohol-less saloons.

Italian Research on Pellagra.—The *Policlinico* states that the government commission for the study of pellagra is now investigating the theory as to the origin and treatment of pellagra advanced by Alessandrini and Scala. Pellagrins will thus be given systematic courses of sodium citrate, on the one hand, and the region will be drained and otherwise treated in prophylaxis on the basis of Alessandrini's theory of the transmission of the disease.

The Campaign Against Alcohol in Russia.—The *Policlinico* of Rome relates that lotions and medicines containing alcohol and denatured alcohol are being consumed in Russia in large amounts since the supply of liquor has been cut off. A number of deaths have occurred in consequence of drinking these substitutes. The prefect of police issued a decree March 31 that no remedies containing alcohol could be dispensed without a physician's prescription. This raised such a storm of protests that the decree was rescinded and a new one issued to the effect that not more than 30 gm. of any medicinal preparation containing alcohol could be sold to one person.

Tobacco Forbidden to All Under Sixteen at Lübeck.—A decree was issued at Lübeck, March 9, 1915, which forbids persons under the age of 16 to smoke tobacco, cigars or cigarets. The parents or guardians of the young people are also held responsible for the enforcement of the decree. The sale of tobacco, pipes, cigars or cigarets to persons under 16 is forbidden, or their supply. The young persons themselves and their parents or guardians are alike held responsible for this. Penalties up to $15 or a jail sentence up to two weeks are provided for infraction of these regulations. The *Medizinische Klinik* comments that the outcome of these regulations, the first of the kind in Germany, will be watched with great interest. Lübeck is a separate state, an independent member of the German empire, a territory of 115 square miles, with a democratic constitution. The anti-tobacco decree is signed by the Public Health Service, the *Gesundheitsamt.*

WAR NOTES

Death of de Cérenville.—The *Revue Médicale de la Suisse Romande* appears with a mourning border on account of the death of the fourth member of its editorial staff, Prof. E. de Cérenville of Lausanne, aged 72. He was for a long time the sole editor of the *Bulletin*, the predecessor of the *Revue*, and a member of the medical faculty of the university.

Hospital Trains Donated to Germany.—Three motor trains for carrying wounded have been presented to Germany by friends in America. Each consists of a motor truck and two trailers, and is equipped to carry ten severely wounded or seventeen slightly injured. One has been despatched to the army under the Crown Prince, another to Hindenburg's army, and the third to the eighteenth army corps.

Italian Inspection of Sanitary Service in German and French Armies.—Prof. B. Rossi of Milan has been making an official tour of inspection of the workings of the army medical and Red Cross service in France and Germany. He was given every facility by the German and French authorities, and has been addressing the profession at Rome since his return.

German Surgical Congress Held at Brussels.—The annual meeting of the German Surgical Association was supposedly postponed on account of the war, but the surgeon-general of the army sent out a recent summons for the meeting to be held at Brussels. Hundreds of surgeons flocked to the meeting, which commenced at Brussels, April 7. All the sessions were devoted to military surgery and a number of new points learned from practical experience were brought out. A fine exhibition of roentgenograms was one of the features of the meeting. Garré, Körte, Payr and Bier delivered the leading addresses.

Aid for Belgian Physicians.—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession, for the week ending May 15, 1915, lists the following contributions:

Dr. Franklin B. Miller, Pittsburgh, Pa.		$ 25.00
Dr. N. S. Jarvis, Captain U. S. A., New York, N. Y.		15.00
Dr. Charles G. R. Jennings, Elmira, N. Y.		23.00
Dr. H. E. Jenkins, P. A. Surgeon, U. S. N., Port Royal, S. C.		5.00
Dr. Luther G. Paul, Boston, Mass.		5.00
Dr. M. C. Smith, Lynn, Mass.		5.00
Arkansas Medical Society, Little Rock, Ark.		50.00
Dr. Charles Henderson Miller, Chicago, Ill.		10.00
Receipts for the week ending May 15		$ 140.00
Previously reported receipts		6,720.50
Total receipts		$6,860.50
Previously reported disbursements:		
1,625 standard boxes of food at $2.20	$3,575.00	
1,309 standard boxes of food at 2.30	3,010.70	
Total disbursements	$6,585.70	
Balance		$ 274.80

F. F. SIMPSON, M.D., Treasurer,
7048 Jenkins Arcade Bldg., Pittsburgh, Pa.

LONDON LETTER

LONDON, April 30, 1915.

The War

AN AUTHORITATIVE MEDICAL HISTORY OF THE WAR

Notwithstanding the tremendous strain on their energies, the authorities have shown commendable forethought with regard to the history of the war. A committee, under the presidency of the director-general of the Army Medical Service, has been formed to provide the necessary coordinating authority for the compilation of an adequate medical history of the war. For each of the chief subdivisions of the work, military and civilian members have been appointed, except in the case of the Section of Hygiene, both members of which are military. The constitution of the committee is as follows: Medicine, Lieut.-Col. O. L. Robinson and Prof. Sir William Osler. Surgery, Lieut.-Col. E. M. Pilcher and Col. F. F. Burghard. Pathology and Bacteriology, Col. Sir William Leishman and Capt. F. W. Andrewes. Statistics, Lieut.-Col. H. P. W. Barrow, Dr. John Brownlee and Lieut.-Col. W. N. Barron. Hygiene and Sanitation, Col. W. H. Horrocks and Lieut.-Col. W. W. O. Beveridge. Historical and Secretarial, Capt. F. S. Brereton and Dr. W. M. Fletcher.

DRINK AND THE WAR: GOVERNMENT PROPOSALS

In a previous letter to THE JOURNAL the effects of drink in interfering with the output of urgently required munitions of war was described. Mr. Lloyd George has brought forward proposals for dealing with it which are moderate and fall far short of the demands of the teetotal party. He could not agree to the total prohibition of whisky, as it is a beverage of particular localities, such as Scotland and Ireland, and the appearance of being unfair should be avoided. The mischief from the drinking of spirits, however, especially in its undiluted form, was incalculable. In order to restrain as much as possible the sale of spirits and of the most alcoholic beer, he proposed to levy a surtax on spirits and on all beers containing more than 7 per cent. of proof spirit. Saloonkeepers are not allowed to sell spirits without notice to the purchaser if they are lower than 25 per cent. underproof. In future the limit would be lowered to 35 per cent. underproof. Wines would be taxed on the same scale, which means quadrupling the duty. In areas producing war material there would be more control on the liquor trade, as in spite of the increased duty the men are earning such wages that they can buy quite enough to incapacitate them. There will be power to close any saloon, the presence of which is considered prejudicial to the output of munitions, the transport of material, or the discipline of the troops. As one of the causes of drunkenness is the fact that men cannot obtain reasonable refreshment near the works, there would be power to use either saloons or other premises for this purpose. There would also be power to suppress the sale of spirits and of heavy beer in these areas.

Vital Statistics: Increase of Cancer

The report of the Registrar General on births and marriages for the year 1913 has just been issued. The delay in publication is explained by the war having decreased the staff of workers in the department. The population of England and Wales at the middle of 1913 is estimated to have been 36,919,339, made up of 17,857,014 males and 19,062,325 females. The marriage rate for the year was 15.5 per thousand, being the same as in the preceding year, and 0.1 above the average in the ten years 1903-1912. The marriage rate in 1912 and 1913 showed an increase on those in the four preceding years. The provisional figures for 1914 indicate a further rise of 0.3 per thousand. The birth rate was 23.9 per thousand, that is, 2.4 below the average for the preceding decennium, and was, with the exception of that of 1912, the lowest on record. The provisional figures for 1914 indicate a further fall of 0.3 per thousand. The death rate, 13.7 per thousand, though higher than in 1910 and 1912, was 1.2 below the average for the ten preceding years. Infant mortality was 108 per thousand births, which was a slight increase over 1912, owing to an increase of mortality from diarrhea and enteritis. Mortality from all the principal epidemic diseases was below the average, that from typhoid fever and whooping cough being the lowest recorded. The death rate of tuberculosis was the lowest on record, and generally the mortality from diseases affecting the lungs was very low. On the other hand, cancer caused a higher death rate among both males and females than in any preceding year. The mortality among single women from ovarian cancer has been twice as great as that among the married, and cancer of the breast 45 per cent. greater; but uterine cancer shows a mortality among married women 73 per cent. higher than among unmarried women. Cancer of the breast is claiming a rapidly increasing number of victims, while uterine cancer is diminishing. As child bearing seems to increase the risk of the latter and diminish that of the former, it is suggested that the phenomenon is connected with the present decrease of fertility.

PARIS LETTER

Paris, April 29, 1915.

The War

SANITATION OF BATTLEFIELDS

At one of the last sessions of the Conseil supérieur d'hygiène publique de France, M. J. Brissac, director of public hygiene under the department of the interior, made an important report on the sanitation of battlefields, especially the removal of dangers to health resulting from the hasty burial of the bodies of human beings and animals.

A mission of inspection ordered by the minister of the interior January 22-25 last determined that the burials of the bodies of soldiers, French, allies and enemies and of the carcasses of horses and cattle have in many cases been done under unsatisfactory conditions, sometimes by the enemy himself, sometimes by our troops, sometimes by inhabitants who have returned to their homes and sometimes under the direction of the rearguard stations and services. The haste with which in most cases these interments have necessarily been made has not always permitted the taking of the proper hygienic precautions. A large number of graves and burial mounds are too near dwelling places, sometimes only a few yards away or have been made as chance may dictate in the midst of cultivated land, or even in the ditches along the roads. In general, these graves are much too shallow. In the cases of many burial mounds, the bodies are covered by a layer of soil not over 20 or 30 cm. (6 or 10 inches) thick. Moreover, when the burial has been made in clayey or marshy soil above shallow subterranean springs, the corpse is not quickly decomposed. The consequences are likely to become serious. Not to speak of the persistent odors of putrefaction, it is inevitable that the graves scattered among cultivable lands will soon be profaned. What is most to be feared, however, is the contamination of underground springs, fountains of potable water and public or private wells.

The administration has, therefore, planned the application, as early as possible, of measures of sanitation in the zones of the extreme rear, to be extended as rapidly as the national territory is liberated. In the first place, the exact location of all the graves and burial mounds in each commune will be ascertained and the data submitted to the geologic service for study with a view of determining the exhumations necessary for the protection of potable waters and inhabited places. The best locations for hygienically unobjectionable reinterment will be determined in advance by the geologists. Wherever possible, the new graves will be grouped in the village cemeteries. The most minute precautions will be taken for the identification of the body, if possible, at the time of exhumation. A record will be kept of all the data tending to identification, and the data recorded will be communicated to the municipalities. Thus all precautions possible will be taken to comply with the legitimate desire of families to identify lost members at the end of the hostilities.

The carcasses of horses, cattle and other animals will be disposed of by treatment with quicklime.

THE THERMAL STATIONS AND THE WOUNDED IN WAR

It is well known that certain posttraumatic articular lesions as well as wounds that cicatrize slowly are greatly benefited by appropriate treatment with mineral waters. Many thermal stations are provided with excellent outfits of mechanotherapeutic appliances capable of doing excellent service in cases of wounds which have healed but which have been followed by functional troubles. Dr. Fluteau, director of the medical service of the sixteenth region, the center of which is Montpellier, has addressed all the head physicians of hospitals within the region, inviting them to send to Lamalou and Balaruc the wounded and sick who are capable of receiving benefit from thermal treatment such as is given at these stations. The director of the medical service has delegated a physician on the staff to arrange with the secretary general of the Institut d'Hydrologie, for the general extension of similar measures.

Dr. F. Garrigou, former professor of hydrology at the Faculté de médecine de Toulouse, has just published in the *Revue* an article in which he mentions that France possesses the richest and most varied mineral springs; the Pyrenees especially possess the most varied sanatoriums in the world within a surface of a few kilometers. It would be possible to care for thousands of patients there.

ASSISTANCE FOR FAMILIES OF PHYSICIANS PLACED IN NEED BY THE WAR

Many families of physicians are now without resources either because of the sudden loss of the head of the family or because they have had to flee before invasion into the interior of the country. Therefore the Oeuvre parisienne de secours immediat et d'assistance à la famille médicale decided at its last general assembly to create a fund for the duration of the war under the heading of Secours de guerre à la famille medicale (war assistance for medical families).

EMPLOYMENT OF GREASED TULLE FOR THE TREATMENT OF WOUNDS

Since dressings of sterilized gauze have the disadvantages of adhering to wounds and of being difficult to detach, it has occurred to M. A. Lumière of Lyons to use compresses of tulle with a mesh of 2 mm. These compresses separated from each other by paper are sterilized by heat for an hour in a mixture composed of petrolatum, wax, castor oil and balsam of Peru. Thus prepared they do not adhere to the wounds while the secretions pass through the meshes of the tulle and are absorbed by the wadding of the dressings.

THE UTILIZATION OF RICE FLOUR IN THE MANUFACTURE OF BREAD

Although our stock of wheat is amply sufficient for the present, it is interesting to mention a communication made during a recent session of the Académie de médecine by Dr. Maurel, professor of experimental pathology at the Faculté de médecine de Toulouse. Maurel advises the use for bread of a mixture of 20 per cent. rice flour to 80 per cent. wheat flour. Such a mixture has no hygienic disadvantages. It gives a bread with nutritive qualities approximately equal to those of pure wheat bread; the loaf, moreover, looks and tastes good.

An important consideration is the fact that our rice from Cochin China offers a means of supplying the deficit in our future harvest of wheat. Maurel believes that the country would make great economy by employing rice flour in this manner, for a million tons of rice flour would cost France only 270,000,000 francs ($54,000,000) while a million tons of wheat flour would cost 420,000,000 francs ($84,000,000).

Dr. Armand Gautier, former professor of organic and inorganic chemistry at the Faculté de médecine de Paris, approves of Maurel's suggestion and suggests that the Japanese war bread, which is the best of all war bread, contains from 10 to 12 per cent. of rice flour. This bread is not subject to attack by insects and keeps its edibility and its good taste almost indefinitely. Notwithstanding, it must be recognized that bread containing rice flour is a little less nourishing than bread composed entirely of wheat since rice contains less gluten than wheat does.

Association News

THE SAN FRANCISCO SESSION

Changes in Schedules of Special Trains

Attention is called to a change in the schedule of the American Medical Direct Route Special which has just been announced. Instead of one train leaving Chicago at 5:30 p. m. Friday, June 18, as previously stated, there will be two trains over this route: first, an extra fare train (extra fare $10), leaving Chicago Friday, June 18, at 7 p. m., and arriving in San Francisco Monday, June 21, at 10:10 a. m., and second, a train leaving Chicago Thursday, June 17, at 9:30 p. m., and arriving in San Francisco at 8:55 p. m. Sunday, June 20. The latter is a regular fare train.

The special train for San Francisco, for members of the Sections on Ophthalmology and on Laryngology, Otology and Rhinology who will be in attendance on the meeting of the American Laryngological, Rhinological and Otological Society, will leave Chicago at 8:05 p. m., June 16, instead of June 15, as originally stated. The itinerary of this train will be the same except that it will be one day later than the schedule previously announced, arriving in San Francisco on Sunday, June 20, instead of on Saturday, June 19.

For the announcement of other special trains, see The Journal, May 15, 1915, page 1707.

Take Extra Wraps to San Francisco

The local Committee on Arrangements desires to emphasize the suggestion already made to Fellows who plan to attend this meeting, that the mornings and evenings in San Francisco are usually windy and chilly and that there may be cold fogs. It is advisable, therefore, for visitors to provide themselves with medium-weight clothing and to have at hand suitable wraps and overcoats.

Deaths

Jerome Henry Salisbury, M.D. Rush Medical College, 1878; a Fellow of the American Medical Association; died suddenly at his home in Wheaton, Ill., May 14, from cerebral hemorrhage, aged 61. He was born in Fitchburg, Wis. He was valedictorian of his class in Wisconsin University, from which he graduated in 1876; soon after his graduation in medicine he began his teaching career as professor of chemistry in the Northwestern University Woman's Medical School, Chicago, later becoming assistant professor of chemistry and then assistant professor of medicine in Rush Medical College. He also occupied the chair of medicine in the Illinois Post-Graduate School. Dr. Salisbury's contributions to medical literature were extensive and varied. His acquaintance with foreign languages, added to his knowledge of medical writings, made him a valued consultant in the editorial positions which he occupied for several years. He was coeditor with Dr. Frank Billings of the Section on General Medicine of the "Practical Medicine Series," and also coauthor with the late Prof. C. S. N. Hallberg of the "Physicians' Manual of the Pharmacopeia." He was also connected with the editorial staff of several other medical publications and since 1907 has been a member of the staff of The Journal. In the latter relationship his kindly manner and sympathetic aid won him the esteem and love of all his associates, who learned to value highly his extraordinary mental faculties and extensive medical knowledge.

Brigadier General William Henry Forwood, M.D., formerly surgeon-general, U. S. Army; University of Pennsylvania, Philadelphia, 1861. In August of the same year he entered the Army as assistant surgeon, and passing through the various grades became brigadier general and surgeon-general on June 8, 1902, and was retired by operation of law on reaching the age of 64 years on September 7, of the same year. He served in the Civil War, in which he was severely wounded in battle. He also served as president of the Army Medical School and was president of Army examining boards. During the Spanish-American War he built and was in charge of the hospitals at Montauk Point, L. I. He was a Fellow of the American Medical Association, the American Academy of Medicine, the Philadelphia Academy of Natural Sciences and many other scientific bodies. He also was professor of surgical pathology in the Georgetown University, Washington, D. C., and professor of military surgery in the Army Medical School. After General Forwood's retirement he made his home in Washington, where he died, May 11, after a prolonged illness, aged 76.

Catherine B. Patrick Slater, M.D. Northwestern University Womans' Medical School, Chicago, 1879; a Fellow of the American Medical Association; president of the Fox River Valley Medical Association in 1901-02; said to have been the first woman physician to gain entrance to the Berlin College of Medicine; surgeon to the Aurora City Hospital and for eighteen years a member of the Board of Education of Aurora, Ill.; died at her home in that city, May 10, from cerebral hemorrhage, aged 71.

Charles Calvin Knight, M.D. New York University, New York City, 1855; a Fellow of the American Medical Association, and the oldest practitioner of Peekskill, N. Y., where he had practiced for more than fifty-seven years; president of the medical board of the Peekskill, N. Y., Hospital; president of the Peekskill Savings Bank and a director of the Westchester County National Bank; died at his home in Peekskill, May 5, from a ruptured aneurysm of the abdominal aorta, aged 82.

Jay Webber Seaver, M.D. Yale University, New Haven, Conn., 1885; a Fellow of the American Medical Association; for twenty years physical director of the Yale University gymnasium; once president of the American Association of Physical Directors and of the Society of College Gymnasium Directors; eminent as a writer on physical development and physical education; died suddenly in Berkeley, Cal., May 6, aged 60.

Ralph Rollin Chase, M.D. University of Minnesota, Minneapolis, 1889; a Fellow of the American Medical Association; local surgeon of the Chicago, Milwaukee and St. Paul Railway at Eau Claire, Wis.; formerly president of the Eau Claire County Medical Society; for nine years health physician of Eau Claire; died at his home, May 4, from cerebral hemorrhage, aged 54.

Frederic Shurtleff Coolidge, M.D. Harvard Medical School, 1891; a member of the Illinois State Medical Society and American Orthopedic Association; a specialist in orthopedic surgery of Chicago; who moved to Pittsfield, Mass., about ten years ago on account of prolonged illness due to infection from an operation wound; died in New York City, May 15, from pneumonia, aged 49.

Robert W. Warner, M.D. Albany, N. Y., Medical College, 1880; a member of the Medical Society of the State of New York; coroner of Herkimer County; health officer of Ilion; first lieutenant and assistant surgeon of the Thirty-first Separate Company, N. G. S., N. Y.; local railway surgeon and postmaster of Ilion from 1898 to 1906; died at his home in Ilion, April 18, aged 56.

Bernard G. Maercklin, M.D. University of Pennsylvania, 1887; formerly a member of the Wisconsin State Medical Society; one of the founders of the Milwaukee Medical College, in which he filled the chair of oral surgery; later professor of oral surgery in Marquette University, Milwaukee; died in the Radium Hospital, Milwaukee, April 30, from carcinoma, aged 67.

Seth Wight Kelley, M.D. Harvard Medical School, 1874; a member of the Massachusetts Medical Society; at one time chairman of the Woburn, Mass., Board of Health; a member of the school board and first president of the board of directors of the Choate Memorial Hospital; died at his home in Woburn, Mass., May 5, from cerebral hemorrhage, aged 66.

George Warren Spencer, M.D. University of Michigan, Ann Arbor, 1878; professor of physiology, dermatology and chemistry in the Cleveland Homeopathic Medical College; dermatologist to the Huron Road Hospital and a member of the general staff of the Cleveland City Hospital; died suddenly at his home in Cleveland, May 1, aged 64.

Alpheus Butts Simmons, M.D. University of Georgia, Augusta, 1884; an honorary member of the Georgia Medical Society and a well known and much esteemed practitioner of Savannah, Ga., who retired from practice several years ago; died at his home in Montgomery Road, Savannah, February 11, from cerebral hemorrhage, aged 50.

William Bell, M.D. United States Medical College, New York City, 1880; formerly a member and president of the Michigan State Board of Medicine and Registration; a practitioner of Ionia County, Mich., for more than forty years; died at his home in Belding, Mich., May 1, from cerebral hemorrhage, aged 68.

Calvin H. Reed, M.D. Starling Medical College, Columbus, O., 1868; a veteran of the Civil War; one of the organizers of, and professor of obstetrics in, the Northwestern Ohio Medical College; for several terms a member of the Board of Education; died at his home in Toledo, May 4, from heart disease, aged 74.

Thomas Shriner, M.D. Jefferson Medical College, 1869; one of the best known practitioners of northeastern Philadelphia; for forty-six years physician to the Penn Widows' Home; a member of the board of managers of the Northern Dispensary; died at his home in Philadelphia, May 2, from heart disease, aged 72.

George Prosser Griffing, M.D. Bellevue Hospital Medical College, 1873; a member of the Medical Society of the State of New York, and for more than forty years a practitioner of the Greenpoint section of Brooklyn; died at his summer home in South Jamesport, L. I., April 5, from heart disease, aged 62.

Archibald Elexis McDonald, M.D. Harvard Medical School, 1865; a member of the Massachusetts Medical Society; a practitioner of Boston for many years; at one time surgeon of the Ninth Infantry, Mass., V. M.; died at his home in Jamaica Plains, Boston, April 28, aged 88.

William Austin Polglase, M.D. Chicago Homeopathic Medical College, 1878; of Brooklyn, N. Y.; formerly lecturer on nervous and mental diseases in the University of Michigan; died in the Presbyterian Hospital, New York City, May 4, after a surgical operation, aged 59.

Robert Cottington, M.D. Rush Medical College, 1877; a member of the Wisconsin State Medical Society; a pioneer practitioner of Chippewa County, Wis., and for several years president of the Board of Education of Bloomer; died at his home in Bloomer, Wis., April 17, aged 67.

Israel Wood Powell, M.D. McGill University, Montreal, 1860; a member of the Legislative Assembly; first president of the Provincial Board of Education and vice-president of the Canadian Confederation League; died at his home in Victoria, B. C., February 25, aged 75.

William Leslie McCandless, M.D. Rush Medical College, 1872; for more than forty years a practitioner of Pinckneyville, Ill.; a banker and postmaster of that city; died in St. John's Hospital, St. Louis, May 2, from pneumonia, aged 66.

Edward Garrett Altvater, M.D. University of Maryland, Baltimore, 1911; assistant at the Baltimore Quarantine Station; died in the University Hospital, Baltimore, May 2, a day after an operation for appendicitis, aged 30.

Patrick S. Donnellan, M.D. Royal College of Physicians and Surgeons, Ireland, 1886; for several years a practitioner of Philadelphia and laryngologist to St. Agnes' Hospital; died at Twyford Abbey, London, England, recently.

Joel Franklin Henry, M.D. Cincinnati College of Medicine and Surgery, 1883; a pioneer practitioner of the Fruitvale section of Oakland, Cal.; died at his home in Fruitvale, May 3, from disease of the kidney, aged 74.

Francis Button Marr, M.D. Cleveland University of Medicine and Surgery, 1869; College of Physicians and Surgeons of Ontario, Toronto, 1871; died at his home in Ridgetown, Ont., February 19, aged 74.

Vincent Cumming Cornwall, M.D. Victoria College, Coburg, Ont., 1867; for a number of years reeve of Omemee, Ont., and warden of the County of Victoria; died at his home in Omemee, March 12, aged 83.

Samuel Sylvester Selvey, M.D. Miami Medical College, Cincinnati, 1869; a practitioner since 1856; in 1877 a member of the Indiana State Legislature; died at his home in Dunkirk, Ind., March 2, aged 82.

Job R. Barker (license, Ohio, years of practice, 1897); for forty-four years a practitioner of Ashtabula, O.; a veteran of the Civil War; died at his home in Ashtabula, May 2, aged 70.

Willard Solomon Gayman, M.D. Miami Medical College, Cincinnati, 1894; died at his home in Canal Winchester, Ohio, March 20, aged 48.

Charles Rolph Clement, M.D. Long Island College Hospital, Brooklyn, 1878; died at his home in Groveport, Ohio, April 30, aged 62.

Marmaduke Allen Wood, M.D. University of Pennsylvania, Philadelphia, 1874; died at his home in Philadelphia, April 28, aged 65.

John H. Bell, M.D. Jefferson Medical College, 1858; a physician and druggist of Due West, S. C.; died at his home, April 19, aged 83.

Joseph D. Larimore, M.D. Medical College of Ohio, Cincinnati, 1868; died at the home of his son in Muncie, Ind., April 28, aged 79.

Gregory Arvide Martin, M.D. University of Vermont, Burlington, 1879; died at his home in Franklin, Mass., March 9, aged 72.

Tazewell Bradley, M.D. Medical College of Virginia, Richmond, 1884; died at his home in Roxbury, Va., February 26.

Clayton A. Button, M.D. University of Buffalo, N. Y., 1888; died at his home in Holland, N. Y., February 24, aged 61.

George Frederick Horn, M.D. Jefferson Medical College, 1914; died at his home in Darby, Pa., April 29, from neuritis, aged 22.

James Alfred Gaffney, M.D. Baltimore (Md.) University, 1898; died at his home in Bridgeport, Conn., April 26, aged 39.

Charles Wilkin Beemer, M.D. Trinity Medical College, Toronto, 1893; died at his home in Kenosha, Wis., May 2, aged 44.

John Cary Wells, M.D. Cincinnati, 1855; died at his home in Birmingham, Iowa, March 6, from heart disease, aged 86.

George W. Gregory, M.D. Albany (N. Y.) Medical College, 1879; died at his home in Elmira, N. Y., February 26.

Eli Wesley Fairman, M.D. Rush Medical College, 1872; died at his home in Brodhead, Wis., March 29, aged 68.

Francis August Schulte, M.D. St. Louis University, 1904; died at his home in St. Louis, February 1, aged 50.

Correction. The notice of the death of Dr. John D. Dickerson of Stockton, Md., which appeared in The Journal of May 1, is incorrect. Dr. Dickerson writes under date of May 10, that he does not know where the report originated.

Marriages

Theresa Chestora Snyder, M.D., Chingtu, West China, to Philip E. Hofmann, M.D., of Shanghai, China, at Tzechow, China, Dec. 16, 1914.

Walter Harold McNeill, Jr., M.D., to Miss Vivian Marguerite Peck, both of Mt. Vernon, N.Y., at Bronxville, N. Y., April 14.

Harold Williams Wiley, M.D., South Haven, Mich., to Miss Helen G. Usher of Newburyport, Mass., at New York City, May 1.

Frederick A. Steele, M.D., Oakland, Cal., to Miss Harriet Martin of Fresno, Cal., at Oakland, Cal., April 27.

George Phippen Sanborn, M.D., to Miss Adalyn P. Henderson, both of Boston, at Methuen, Mass., May 7.

Mable C. Lawrence Faulds, M.D., to Mr. Henry Williams, both of Gary, Ind., at Crown Point, Ind., May 4.

Arthur Husser, M.D., Hingham, Mont., to Mrs. Bertha Rachel McCrary of Havre, Mont., April 20.

George Cyrus Kindley, M.D., to Miss Florence May Goodman, both of Galveston, Tex., May 18.

Herbert T. Barnes, M.D., Pewaukee, Wis., to Miss Hazel Ryan of Fond du Lac, Wis., April 28.

William J. Carson, M.D., Atlanta, Ga., to Miss Elizabeth Gunning of Cumberland, Md., May 4.

Hugh P. Dorsey, M.D., Chicago, to Miss Guila Grace Chatron of Capac, Mich., May 4.

Max William Trentzsch, M.D., to Miss Leone Kreul, both of Highland, Wis., April 27.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

VENARSEN

Report of the Council on Pharmacy and Chemistry

The report which appears below was sent to the Intravenous Products Company for consideration. Having considered the firm's reply, the Council has authorized publication of its report along with the explanation sent by the Intravenous Products Company in reference to the variable composition reported for Venarsen, namely, that "only the first few experimental ampoules, sent to the doctors for clinical tests, were made without the Mercuric Iodide."

W. A. Puckner, Secretary.

This product is prepared by the Intravenous Products Company, Denver. The advertising circulars contain inconsistent statements as to its composition. According to one circular Venarsen is

> ". . . a comparatively non-toxic organic arsenic compound, 0.6 Gm. representing 247 Mg. (3¾ grains) of metallic arsenic in chemical combination. . . ."

According to another circular Venarsen is

> ". . . a comparatively non-toxic organic arsenic compound, 0.6 Gm., representing 247 Mg. (3¾ grains) of metallic arsenic and .78 Mg. (3/250 grain) metallic mercury in chemical combination."

Neither one of these statements gives any information as to the actual composition of the product. Inquiry addressed to the manufacturers elicited the reply that:

> "Venarsen contains in each 5 c.c. 0.6 Gm. Sodium Dimethyl Arsenate, .0016 grams of Mercuric Iodide, .0048 grams of Sodium Iodide in solution in a suitable vehicle for intravenous administration."

The following report of the examination of Venarsen is submitted by the Association's Chemical Laboratory:

LABORATORY REPORT

Three ampules of Venarsen were examined. The first ampule was labeled

> "A comparatively non-toxic organic arsenic compound, representing 247 Mg. (3¾ grs.) of metallic arsenic in chemical combination. 5 c.c. — 0.6 Gm."

Practically the same statement appeared in an advertising circular wrapped around the ampule. The second and third ampules bore labels identical with the first. The circulars differed from that accompanying the first ampule in that the presence of mercury is also announced, thus:

> "Venarsen is a comparatively non-toxic organic arsenic compound, 0.6 Gm., representing 247 Mg. (3¾ grains) of metallic arsenic and .78 Mg. (3/250 grain) metallic mercury in chemical combination and is so prepared and enhanced as to present the ingredients to the blood in their most acceptable form."

Thus, although the potent elements said to be contained in Venarsen are named, its chemical character (the combination in which the elements occur) is not disclosed.

The ampules contained a transparent, odorless solution, possessing the yellow color of salvarsan solution (an aqueous solution of sodium cacodylate, mercuric iodid and sodium iodid in the amounts said to be present in Venarsen is colorless). Qualitative tests demonstrated the presence in each of the three ampules of sodium cacodylate (sodium dimethyl arsenate), and the absence of arsenites, arsenates, phosphates, arsanilates (atoxyl, soamin) and arsenphenolamins (salvarsan, neosalvarsan). Titrated with normal hydrochloric acid, using methyl orange as indicator (as outlined in New and Nonofficial Remedies, 1915, p. 40), the three ampules were found to contain the equivalent of respectively, 0.219, 0.253 and 0.216 Gm. or an average of 0.244 Gm. arsenic. (According to statements of the firm each 5 c.c. of Venarsen contains 0.6 Gm. sodium dimethyl arsenate (sodium cacodylate), equivalent to 0.247 Gm. arsenic or 41.66 per cent. Sodium dimethyl arsenate, as described in New and Nonofficial Remedies, contains 3 molecules of water and 35 per cent. arsenic. This indicates that the sodium dimethyl arsenate used in Venarsen contains less water of crystallization than the N. N. R. product).

Neither mercury nor iodid could be found in the first ampule. (The company has since explained that mercury was absent only from the first experimental samples.) The second and third ampules contained iodid and mercury in small amount. The exact quantity was not determined because, on the basis of the mercury content declared, a single accurate mercury estimation would have required the purchase of something like 25 to 100 ampules. As each ampule sells for two dollars, the cost of the material was considered prohibitive.

From the foregoing we conclude that the first ampule examined consisted essentially of a solution containing 0.625 Gm. of sodium cacodylate, N. N. R., while the second and third ampules contained 0.722 Gm. and 0.617 Gm. sodium cacodylate, respectively, and in addition, a mercury compound, probably mercuric iodid, dissolved by sodium iodid.

In other terms, Venarsen as now marketed is a simple solution containing approximately 9 grains of sodium cacodylate, 1/40 grain of mercury "biniodide" and ¾ grain of sodium iodid to each full dose.

In the past the preparation has been in conflict—especially serious because of the potent character of the drug—with Rule 1 (secrecy of composition). The manufacturers have removed this conflict by furnishing a statement of composition; and it is to be expected that they will likewise take steps to remove the manifestly erroneous impression now likely to be gathered from the circulars, namely, that the preparation is rather analogous to salvarsan. These conflicts, however, call for comment, since physicians have doubtless used the material under misapprehensions.

As to therapeutic claims, the preparation is said to be effective and safe in syphilis; "lower toxicity and greater spirochaetacidal power than other known arsenic compounds" are among the claims. No real evidence for either of these claims is presented. Sodium cacodylate has been tried as an antisyphilitic, but with indifferent success; certainly the results have not been comparable to those of salvarsan. The mercury could conceivably enhance its effect, but the dosage appears too small and the course too short for this influence to be pronounced. Moreover, a careful physician would not give arsenic and mercury in fixed proportions.

The claim of comparative non-toxicity is probable enough from what is known about the cacodylate. No physician should feel "safe," however, when injecting intravenously 0.6 gm. of sodium cacodylate every four to six days. Aside from the grave dangers of intravenous injection in general, the possibility of idiosyncrasies to arsenicals should always be borne in mind.

Finally, Venarsen is claimed to be "indicated" in pellagra, tuberculosis, anemia, etc. No evidence is presented on which to base an opinion as to its efficiency in pellagra. Those who have studied that disease would not be likely to resort to this treatment. In tuberculosis and anemia, there is no sufficient advantage in giving the cacodylate intravenously.

To summarize, Venarsen treatment consists essentially in the intravenous injection of large doses of sodium cacodylate. The other ingredients, as well as the name, merely constitute so much mystification. While the cacodylate probably has some effect on the conditions for which it is advised, there is no evidence that its value even approaches that of salvarsan in syphilis, or that the intravenous use is preferable to the ordinary methods. The dangers are manifest, although they may not be so great as with salvarsan. No justification has been established for its use in tuberculosis and pellagra.

Physicians who wish to try intravenous cacodylate administration should have a full realization of the dangers of such treatment, and in order to avoid further risks, will do well to refrain from combining other drugs with the cacodylate in fixed proportions.

It is recommended that Venarsen be held in conflict with Rule 6 (unwarranted therapeutic claims), Rule 7 (poisonous ingredients not stated on label), Rule 8 (name does not express the chemical composition) and Rule 10 (unscientific combination) and that this report be published.

Correspondence

Wassermann Reaction as a Clinical Test

To the Editor:—On page 1463 of The Journal for May 1, 1915, Dr. Heimann discusses several statements made in my contribution to The Journal of March 6. Of the many reasons for scientific discussion, that which holds the place of second importance is the speaking of different languages; and this I take to be the cause of the present disagreement.

The object of my contribution was not to enforce the generally accepted rules of Wassermann evidence, but rather to call the attention of the practitioner to a few relatively exceptional points not always clearly understood. Had Dr. Heimann written his contribution in advance of my own, I might, indeed, have taken it for a text.

Let us consider his conclusions:

> "1. The Wassermann is negative at times in active syphilis, but only under definite and characteristic circumstances, and when this is understood, no confusion should arise."

Surely no practitioner could admit the universal truth of such a statement. It is well known that the gravity of the Wassermann reaction, though it usually runs almost parallel with the gravity of the known somatic lesions, does not quite parallel them. Quite recently I have seen two cases, the one with a pustular, the other with a papular skin lesion, both with negative Wassermanns, both promptly cured by antisyphilitic treatment (one verified by biopsy). By no combination of "definite and characteristic circumstances" can the negative Wassermann in such cases be predicated.

But this point is much more brilliantly illustrated by the doctor's second conclusion:

> "2. The Wassermann test may be positive in the absence of syphilis, in certain other diseases, and under certain conditions easy to recognize and exclude."

So far as I know only one single series of over 100 cases supposedly nonsyphilitic and tested by the Wassermann reaction has revealed results that the reporter could fully explain. Inevitably there crops up the small percentage of cases with no vestige of the disease, but with a positive Wassermann reaction.

It has, indeed, been generally accepted that some 1 or 2 per cent. of males infected with syphilis give no early history, and the worst that has been alleged of any American or highly civilized European community is that some 10 per cent. of its citizens are syphilitic. If but 2 per cent. of these syphilitics do not know they are diseased, we may expect an error of two per thousand in our Wassermann reactions on supposedly healthy males. The actual error is anywhere from twenty times as much upward.

Dr. Heimann's final conclusion is that "matrimony should be withheld from individuals with a positive Wassermann test." With this conclusion I most heartily disagree. I recognize the dangers that threaten the syphilitic with a positive Wassermann reaction far more clearly, I think, than Dr. Heimann does those that threaten the syphilitic with a negative Wassermann reaction. Neither can be guaranteed absolutely safe from relapse in his own person. We need not pretend to disagree on the necessity of exerting every effort to make the Wassermann reaction negative, whether the patient is to be married or not. But this is purely a personal matter of fortifying the patient himself against possible relapse of his disease.

Although we all know that every lesion of syphilis is caused by spirochetes, and that sections from syphilitic tissue removed from a patient many years diseased are infectious when injected into monkeys, yet the clinical fact remains that the lapse of time sufficient to carry the patient beyond the period when he is likely to have eroded papules in the mouth or in the genitals will assure him against the possibility of infecting better than any early demolition of his positive Wassermann reaction. That syphilis may be transmitted from husband to wife after the fifth year of disease is perfectly well known as a clinical rarity, to be looked for only in those patients with persistent relapses of the secondary type; relapses that, of all others, are the most controllable by our modern methods.

But what I am arguing for is mercy to the unfortunate individual whose Wassermann reaction remains positive in spite of our most furious efforts to keep it negative. I do not feel that his positive reaction should stand in the way of matrimony after a sufficient time has gone by to protect his wife from infection.

When all is said and done, however, the difference between Dr. Heimann's point of view and my own is perhaps that infinite difference between those who are dazzled by the splendors of twentieth century science and make science a creed; regard her tentative hypotheses as certainties; her Wassermann reactions such that "no confusion should arise" in their interpretation—between them, on the one hand, and on the other hand those clinicians who, while acclaiming with great joy all the help that science can offer, do not feel that the microscope lends infallibility to the eye or the test tube to the finger. To these seekers after the grain of truth which lies hidden in the turbulent forefront of scientific progress, I submit my case.

Very possibly my contention is quite wrong, but wrong or not, I know—nothing.

Edward L. Keyes, Jr., M.D., New York.

Stay Stitch for Deep Wounds

To the Editor:—In The Journal, April 17, 1915, p. 1317, under the caption, "A New Stay Stitch for Deep Wounds," Dr. Edmond Bonnot of St. Louis describes and illustrates a stitch which I have been using for many years and which has been adopted by many of my colleagues. By some it is named for me, but it is not mine. I saw it described years ago, but have forgotten the name of the magazine and the author, remembering only that it came from one of the nearer Southern States, perhaps Virginia. I have called it the mattress suture on edge, have described it frequently while operating before my classes at Bellevue and elsewhere, and have always taken pains to disclaim any credit for its invention.

It is a useful stitch, particularly in all locations in which there is a tendency for edges to be inverted, along median depressions, over the sacrum, over the sternum, indeed, in almost any place where the skin is thick. It is also of value where the tissues are relaxed, for instance, in perineal sutures, because, no matter how much the tissues are folded, the edges cannot be turned in. As a rule, I use three or four in the ordinary celiotomy incision, afterward closing the edges of the skin with a running suture of fine intestinal silk. I think Dr. Bonnot's suggestion, that it should be tied over tubing, takes away a good deal of its value, because the tubing is liable to cause eversion of the edges of the skin, and one wants neither eversion nor inversion.

George David Stewart, M.D., New York.

Deaths from Laxative Tablets Containing Strychnin

To the Editor:—The coroner of Macon County reports four deaths of children in the last four years from eating laxative tablets containing strychnin; in addition to this I have knowledge of several other near deaths from the same cause. If this is the report for one county in Illinois, what must be the fatalities in the United States where the use of the favorite "A. S. B." and the "Hinkle" tablet, each containing 1/60 grain of strychnin, is so common?

The red color of the Hinkle tablet is especially attractive to children, and in one of the fatal cases reported, the victim had eaten fifteen of these tablets; the poison or caution label on the box had no deterrent effect on either the child or the careless mother. The thought occurred to me, Why put strychnin in laxative tablets, and of what value is strychnin in these combinations? Admitting the value of strychnin in repeated doses in atonic conditions of the intestines, of what value can the usual single evening dose of 1/60 grain have?

In the fatal cases also the toxic effect of the belladonna was very evident. With the large number of nonpoisonous laxatives available, such as cascara, aloin, rhubarb and phenolphthalein, there is no sense in adding the poisonous strychnin.

I am sure that the child's welfare societies can do no better work than to check this useless "slaughter of the innocents" through the use of these strychnin-containing laxative pills or tablets. Everett J. Brown, M.D., Decatur, Ill.

[Comment.—Accidents of the character reported have frequently occurred in the past. There seems to be no remedy, except to urge greater care on the part of physicians who prescribe these preparations and on the part of parents and others who keep them on hand. It would be of decided advantage if these small but dangerous pills or tablets could be dispensed in containers—phials—of special shape, with the word "POISON" distinctly marked on the container; certainly there should be some method of marking that would definitely indicate the dangerous character of the contents. —Ed.]

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ACONITE IN PNEUMONIA

To the Editor:—Will aconite or its alkaloid break up pneumonia?
J. M. Ousley, M.D., Lost Creek, Tenn.

Answer.—The older pathology of pneumonia regarded it as an intense disturbance of the circulation which eventuated in an inflammatory exudation into the alveoli of a fibrinous mass containing a large number of red blood cells and a proportionally larger number of leukocytes. The initial congestion was regarded as due to the deranged action of the heart and blood vessels. Hence it was believed by many that if we could overcome or oppose this abnormal change in the circulation, the disease could be aborted. This was the basis for the practice of bleeding in the early stages, of the use of blisters, of local bloodletting and of the administration of aconite and veratrum viride. The use of these remedies has been compared to bleeding; an old saying has it that by aconite we bleed the patient into his own veins.

With a later conception of pneumonia as an infectious disease, the use of such measures becomes less rational. We now conceive of the congestion as a reaction on the part of the general system against the presence in the lung of bacteria, some of which have usually penetrated from the alveoli into the blood accompanied by their toxins, which incite the nervous system and through it the circulation to throw out an exudate of blood to destroy the micro-organisms and neutralize their toxic products. Under this conception we do an injury and hinder the recuperative processes of nature when we attempt to hinder this application of a curative serum to the invading bacteria.

Experience has shown that pneumonia patients do as well or better without the depressing measures designed to weaken the heart and lessen the congestion, by retarding the circulation or diverting the blood elsewhere. Attempts to abort pneumonia have proved futile. Some observers have thought that they were able by means of aconite or veratrum viride to check the disease in its first stage. There is no reliable evidence that warrants such belief.

DENTAL CLINICS

To the Editor:—Can you give me information as to cities in which dental clinics have been established by a board of education directly, or in connection with a board of health? Also, what success has met their efforts and what opposition has been encountered on the part of the parents? I would furthermore be interested in any details with which you might supply me in the establishment or management of such institutions. R. B.

Answer.—Through Dr. W. G. Ebersole, secretary and treasurer of the National Mouth Hygiene Association, Cleveland, and others interested in mouth hygiene, the following information has been obtained:

Cleveland has seven dental clinics. These are supported by an auxiliary of the National Mouth Hygiene Association and by funds raised by the principals of the schools of that city. Cincinnati has three clinics supported by the municipality. Detroit has ten clinics operated under the board of health and financed by annual appropriation. Rochester has four clinics. Formerly these were supported by the local dental society, but recently the municipality has made appropriation for the work. Buffalo has four clinics supported by the municipality. Philadelphia has several clinics supported by the city. New York City has a number of school clinics maintained by the board of education, and there are four clinics in connection with the various hospitals, maintained by cooperation of the dentists and various philanthropic organizations of that city. Morristown, N. J., has recently established a school dental clinic supported by the united efforts of the dentist and welfare organizations of that city. Several years ago the Odontographic Society of Chicago organized dental clinics in connection with a few of the schools. Later Mr. Julius Rosenwald equipped seven clinics and the dentists three others. For one and one-half years Mr. Rosenwald supported these ten clinics. In 1914 the city took them over, employing ten dentists at a salary of $100 a month each, for ten months in the year. Dr. Molt, a dentist, is a member of the board of health, and has special charge of the dental clinics.

Other clinics are being organized by the National Mouth Hygiene Association in Canton and Dayton, Ohio; Kansas City, Mo.; Louisville, Ky.; Joliet, Ill.; Washington, D. C.; Jacksonville, Fla.; Atlanta, Ga., and Lynchburg, Va.

The work of the established clinics seems to progress reasonably well, but the clinics are wholly inadequate to the needs of the communities in which they operate, since only a small percentage of the children needing dental attention in large communities can be served owing to the lack of funds and dentists. Antagonism by parents against examination and care of their children's teeth is not serious, and need deter no one from entering on this work.

Further information as to the methods of organization and management of dental clinics may be obtained from Dr. W. G. Ebersole, Secretary National Mouth and Hygiene Association, Schofield Building, Cleveland, Ohio.

DEPENDENCE OF DISEASE ON FAULTY DIGESTION

To the Editor:—Has any physician of recognized authority ever stated, or intimated in any way, that from 75 to 90 per cent. of all diseases are due primarily to faulty digestion, or that a derangement of the digestive organs is the first cause of that percentage of diseases? In other words, if digestion and physical resistance were normal, would it render us immune from 90 per cent. of the present diseases?

An answer to this, or any information as to how far a derangement of the gastro-intestinal canal, and organs bearing direct relation to the same, is responsible for the onset of disease, or its first cause, will be very gratefully received. J. W. Lowe, M.D., Mentor, Ohio.

Answer.—So far as can be determined, no authority has published a statement that from 75 to 90 per cent. of diseases are due primarily to faulty digestion. Apparent health and good digestion are not proof against infections, since persons in robust health may fall victims to infectious diseases. An abnormal state of the mucous membrane of the gastro-intestinal tract in certain cases renders it more liable to permit the entrance of micro-organisms and toxins which may cause systemic symptoms, but there is little evidence that this abnormal condition is necessarily associated with any definable disease of the gastro-intestinal tract. It is probable that the healthy digestive tract permits the entrance of poisons in certain cases, without suffering any immediate damage. Lead may produce disorders of the nervous system, although the intestine through which it is absorbed is not affected. In the present state of our knowledge, it would be impossible to say what percentage of disease is due to imperfection in the digestive processes or disease of the digestive organs.

SHORTENING OF THE WORD "FEEBLEMINDEDNESS"

To the Editor:—I have understood that among some writers the word "feeblemindedness" is being shortened to "feeblemindness." It has appeared in a recent issue of the *Survey*. Do you know of any authority for such a simplification, which seems to change the force and sense of the word? G. S., M.D., New York.

Answer.—We know of no authority for shortening the word "feeblemindedness" by omitting the participial suffix. As our inquirer states, such a change is a radical departure, and somewhat modifies the sense of the word.

Michigan Reciprocity Report

Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports that 18 candidates were licensed in Michigan, through reciprocity, from Jan. 11 to April 16, 1915. The following colleges were represented:

College	Year Grad.	Reciprocity with
Northwestern University	(1911) (1914)	Illinois
Rush Medical College	(1894) New York; (1902)	Indiana
University of Illinois	(1913,2)	Illinois
University of Louisville	(1910)	Kentucky
University of Maryland	(1909)	Maryland
Harvard University	(1909)	Maine
Univ. of Michigan, Dept. of Medicine and Surgery	(1910)	Washington
St. Louis College of Physicians and Surgeons	(1910)	Texas
Cleveland College of Physicians and Surgeons	(1911)	Ohio
Miami Medical College	(1908)	Ohio
Pulte Medical College	(1889)	Kentucky
Jefferson Medical College	(1905) New Jersey; (1912)	Illinois
Medical College of the State of South Carolina	(1908)	S. Carolina
Marquette University	(1914)	Wisconsin

California January Reciprocity Report

Dr. Charles B. Pinkham, secretary of the Board of Medical Examiners of the State of California, reports that 27 candidates were licensed through reciprocity at the examination held at Sacramento, Jan. 12-13, 1915. The following colleges were represented:

College	Year Grad.	Reciprocity with
College of Physicians and Surgeons, San Francisco	(1911)	Nevada
Columbian University	(1902)	Washington
George Washington University	(1914)	Dist. Colum.
Chicago College of Medicine and Surgery	(1910)	Penna.
Hahnemann Medical College and Hospital, Chicago	(1897)	Illinois
Northwestern University	(1906,2) (1914)	Illinois
Rush Medical College	(1904) (1908) Arizona; (1900)	Illinois
University of Illinois	(1914)	Illinois
Johns Hopkins University	(1902)	Montana
University of Michigan, Dept. of Med. and Surg.	(1907)	Michigan
University of Minnesota	(1891)	Minnesota
Barnes Medical College	(1897)	Michigan
St. Louis College of Physicians and Surgeons	(1906)	Illinois
University Medical College, Kansas City, Mo.	(1904)	Kansas
John A. Creighton Medical College	(1911)	Nebraska
College of Phys. and Surg. in the City of New York	(1906)	New York
Homeopathic Med. Coll. of the State of New York	(1868)	New York
Long Island College Hospital	(1876)	Wisconsin
Syracuse University	(1876)	U. S. Army
University and Bellevue Hospital Medical College	(1903)	New York
University of Buffalo	(1903)	New York
Willamette University	(1905)	Washington
Medical College of Virginia	(1914)	Virginia

Iowa January Report

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, Jan. 19-21, 1915. The total number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 13, of whom 11 passed and 2 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago College of Medicine and Surgery	(1914) 88, 94,	94
Hahnemann Medical College and Hospital, Chicago	(1908)	89
Northwestern University	(1911) 90; (1912) 93; (1913)	91
University of Illinois	(1914)	89
Hospital College of Medicine, Louisville	(1885)	82
Harvard University	(1915)	90
John A. Creighton Medical College	(1914)	87
FAILED		
Hahnemann Medical College and Hospital, Chicago	(1909)	82*
Rush Medical College	(1885)	75*

* Conditioned in one subject.

Wisconsin January Report

Dr. John M. Beffel, secretary of the Wisconsin State Board of Medical Examiners, reports the practical and written examination held at Madison, Jan. 12-14, 1915. The total number of subjects examined in was 24; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 19, of whom 13 passed and 6 failed, including 1 osteopath. Twenty-eight candidates, including 6 osteopaths, were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
George Washington University	(1907) 84; (1914) 84,	84

Book Notices

John Shaw Billings: A Memoir. By Fielding H. Garrison, M.D. Cloth. Price, $2.50. Pp. 432, with illustrations. New York: G. P. Putnam's Sons, 1915.

If those of us who were practicing medicine twelve or fifteen years ago were asked to-day what John Shaw Billings had done to make him so well known, many of us, we feel very sure, would answer that his great life work was that connected with the Surgeon-General's Library at Washington, and with those wonderfully practical guides to medical literature, the "Index Catalogue of the Library of the Surgeon-General," its offshoot, the "Index Medicus," and the "National Medical Directory." And we would be justified in this, for he practically created that library, and was at its head for nearly a third of a century; in more senses than one, he made the "Index Catalogue," and was responsible, with the late Dr. Fletcher, for the "Index Medicus." These accomplishments are certainly worthy of commemoration. Still, these were mere incidents in the life work of John Shaw Billings, as one will realize on reading this biography.

To John Shaw Billings, more than to any other man except the donor himself, must be given the credit for Johns Hopkins Hospital and Medical School. He it was who worked out the general plans of the buildings and superintended their construction. He it was, also, who worked out the underlying principles on which the combined institutions, the hospital and medical school, should be and are conducted. He had much to do, too, with the selection of at least two of the faculty, Dr. W. H. Welch and Dr. William Osler. A most interesting chapter in this biography is that describing the founding of Johns Hopkins Hospital.

Then again, his connection with the Medical Department of the University of Pennsylvania, 1891-1896, is known to but few, and yet here he left his impress. He was selected as the director of the Laboratory of Hygiene, which he planned, and of the University Hospital. He was lecturer on, and later professor of hygiene and vital statistics. Except for the last year, his work in Philadelphia was carried on in connection with his Washington duties; but in 1895 he moved to Philadelphia, intending to make that his future home and his duties at the University of Pennsylvania his life work.

Within a year, however, he was called to do bigger things—he was invited to take charge of the New York Public Library. Simply stated, this sounds and means little; actually, the magnitude of the undertaking was stupendous. It meant the consolidation of the Astor, Lenox, Tilden and other great libraries into one, that one to be equal in magnitude and superior in arrangement to any library anywhere in the world. It meant working out a general scheme for a library whose initial number of books aggregated over 350,000 volumes, and whose ultimate number was to be "on a footing with the British Museum, with nearly two million books, or the Bibliothèque Nationale of France, with its three million." It meant also planning the buildings and overseeing, in a general way, their construction.

In 1905 "he was engaged by the corporation of the proposed Peter Bent Brigham Hospital in Boston to lay out . . . plans for suitable buildings for a hospital to accommodate at least two hundred beds, and a general scheme of organization, and details regarding its alliance with Harvard University." This work required three years, and was supplementary to that in connection with the New York library.

When the Civil War broke out, Dr. Billings was demonstrator of anatomy in the Medical College of Ohio, and was beginning to get considerable surgical practice. As his biographer says, "Billings would no doubt have become one of the leading surgeons of Cincinnati, and of the United States"; but his career, like that of thousands of others, was changed by the war. He joined the medical corps of the U. S. Army, with which he remained for over thirty years. About a third of the book is devoted to an account of his experience and work in the army. His war journals follow Grant's campaign of 1864 very closely and minutely. The finished account of the Battle of the Wilderness on pages 128 and 129 (from McParlin's report, but probably written by Billings himself) may have given some points to the later historians. While his life and work in the field were, on the average, the same as that of other army surgeons, one faculty seems to have revealed itself in Dr. Billings at the very beginning—that of organization; the opportunity was construction and management of base and field hospitals.

Few men have had a greater influence on medical education in this country. As already stated, to him as much as to any one, is due the high standard adopted by Johns Hopkins at its beginning, as well as the practical and stimulating methods of instruction inaugurated by that institution. If such a man can be said to have specialized in any branch, Dr. Billings specialized in public hygiene. At least until he undertook the great work connected with the New York library, his main efforts were expended on matters of public health.

The biography of men who have done things is always instructive and informing, especially if the biography is what it should be. This is the case here. We are given a history of the development of the Surgeon-General's Library from the day of small things to what it is today; of the growth of a small alphabetical list of books to the immense "Index" of today; of the creation and demise of the National Board of Health, which was "in a sense premature, as being forced into existence through a yellow fever scare." We are given the essential facts connected with the origin and development of Johns Hopkins Hospital and Medical School, of the Laboratory of Hygiene of the University of Pennsylvania, and of the Peter Bent Brigham Hospital of Harvard. Of much public but of less medical interest is the history of the great New York Public Library. With working up of the plans of each of these institutions, Dr. Billings went to Europe to study similar institutions of the Old World. This gave him a broad view of things, and introduced him to many of the principal workers there. We get little regarding these trips, except quotations from letters to Mrs. Billings and to a few friends; one wishes there could have been more, but evidently he was not a letter writer. One wishes also that there might have been more of the intimate life of the man in his home, among his close friends; but this, presumably, was impossible. Dr. Garrison has done a service to American medicine in giving us this account of one of the influential men in the medical profession of the United States. We believe we are not overstating when we say that this is one of the most valuable additions to medical biography and to American medical history that has thus far been made, if not the most valuable one.

The History of Smallpox in Australia, 1788-1908. Compiled from Various Sources by J. H. L. Cumpston, M.D., D.P.H., Director of Quarantine. Paper. Pp. 182. Melbourne: Government Printer, 1914.

Quarantine Service Publication No. 3 of the Australian Commonwealth gives a history of smallpox in that country from its settlement in 1788 to 1908. Though the records are incomplete, there is in this publication much detailed information gathered and compiled from various sources. There are recorded imperfect histories of three distinct and fatal epidemics of the disease among the aborigines since the opening of the country, and eleven epidemics among the population in the settlements. The latter epidemics have been small, the largest including only about 154 cases, and the total number of cases down to 1908 amounting to only about 500. In almost all instances the disease has been introduced by vessels plying at the various ports, though it has been endemic to a slight extent since its first introduction. The disease has been introduced 182 times in a period of eighty years. It has shown a very short range of infection, as a rule, in Australia, and actual personal contact is ordinarily necessary for infection. Interesting is the suggestion of Dr. McCrae of the Central Health Board of Victoria, in 1872, of the agency of flies in the spread of smallpox. On account of the small number of cases, the factor of exhaustion of susceptible material has not applied to Australia, and vaccination, even at present, is not compulsory in all of the states, some having practically no legislation with reference to this measure. The history of such legislation is given in the report. Estimates made from the imperfect data available indicate that in the last fifty years about 32 per cent. of the population have been vaccinated. The effects of vaccination in the epidemics recorded are in line with the history of vaccination in other countries, the vastly largest percentage of the mortality, which has not been great, occurring among the unvaccinated, next among those not revaccinated within the recognized period of immunity, and least among the recently vaccinated or those revaccinated within a proper interval before exposure. Among the latter it is said that almost permanent immunity is attained. The report does not include the history of the last epidemic in 1913, which was, like the others, shipborne into the country.

An Introduction to the Study of Color Vision. By J. Herbert Parsons, D.Sc., F.R.C.S., Ophthalmic Surgeon, University College Hospital, London. Cloth. Price, $3.75 net. Pp. 308, with 75 illustrations. New York: G. P. Putnam's Sons, 1915.

In this book, which is the most recently published treatise on the subject of color vision, the author wisely deals with facts first and theories later. In a natural order of procedure, Part I of the book describes the chief facts of normal color vision from its physical, anatomic and psychologic bases. Then follows the spectrum as seen both by the light-adapted and the dark-adapted eye, and the various phenomena and color effects on the retina. The last section of Part I considers the evolution of color vision, including the development of color vision in the child, and containing also an interesting chapter on comparative psychology of color vision. Part II takes up the chief facts of color blindness, with brief historical references. Part III is devoted entirely to the various theories of color vision. Realizing that no theory has ever been advanced which explains all the facts of this department of science, the author takes up briefly the theories which still have followers, pointing out the strong as well as the weak features of the different ones. Researches based upon the Young-Helmholtz and the Hering theories are described. In conclusion there is briefly outlined a description of seven of the most recently advanced theories of color vision. The book is a valuable contribution to the literature of color vision, particularly because the author treats of the various theories from an absolutely unbiased point of view, which cannot be said of the majority of writers on this subject.

Clinical Diagnosis. A Manual of Laboratory Methods. By James Campbell Todd, Ph.B., M.D., Professor of Pathology, University of Colorado. Third edition. Cloth. Price, $2.50 net. Pp. 585, with 179 illustrations. Philadelphia: W. B. Saunders Company, 1914.

The scope of this book has been enlarged and its size increased in order to permit the inclusion of many important advances in laboratory technic. Each section has been carefully revised, additions being especially made to those on sputum, urine and animal parasites. Among the newer methods noted are Weisz' test for urochromogen, Ponder's stain for diphtheria bacilli and the urease method for urea. A new chapter on serodiagnostic methods has been added by Dr. Ross C. Whitman. While this manual is not so complete as many of the works on clinical diagnosis, it is sufficiently comprehensive for the student (for whom it is intended) and for the general worker who may wish to become familiar with the more common as well as with the newer methods of laboratory examination. The text is clear and concise. The illustrations are adequate and instructive.

Lead Poisoning from the Industrial, Medical and Social Points of View. Lectures Delivered at the Royal Institute of Public Health. By Sir Thomas Oliver, M.A., M.D., M.R.C.P., Attending Physician, Royal Victoria Infirmary. Cloth. Price, $2. Pp. 294. New York: Paul B. Hoeber, 1914.

This book consists of lectures delivered by Dr. Oliver at the Royal Institute of Public Health, London. The author has had a wide experience and has made a special study of lead poisoning. His book will be of value to all interested in the subject. In the appendix are published the factory and work shop orders, as used in England, relating to lead poisoning.

Malpractice in Treatment of Oblique Fracture of Clavicle—Care Required—Amount of Damages

(Craghead vs. McCullough (Colo.), 146 Pac. R. 235)

The Supreme Court of Colorado affirms a judgment in favor of the plaintiff for $650 damages for alleged malpractice in the treatment of an oblique fracture of the clavicle. The court says that, briefly, the defendant's treatment consisted in putting the ends of the bone in place and bandaging and holding the arm and shoulder in a position with the aid of a fulcrum, the object of this treatment being to prevent overlapping. All the surgeons called as witnesses who testified on the subject stated that the method employed was the usual and proper one to treat such a fracture. Employing the method to reduce a fracture generally recognized by surgeons as proper is not negligence. But there was substantial testimony from which to deduce one of two conclusions; either the defendant did not place the fragments in proper place in the first instance, or, if he did, he failed to exercise ordinary care from time to time to ascertain whether they remained in place and in keeping them in proper position. In the absence of a special contract, the law implies that a surgeon employed to treat an injury contracts with his patient that he will exercise reasonable and ordinary care to accomplish the purpose for which he is employed. He does not warrant a cure and is not responsible for want of success, unless it results from a failure to exercise ordinary care, or from want of ordinary skill. True, as stated in many well-considered cases, the failure to exercise ordinary care in treating a fracture is not established by proof of the result alone, but must be shown by other evidence. The original verdict was for $1,000, but, while a motion for a new trial was pending, the plaintiff filed a remittitur of $350. The court does not think that the verdict was excessive. That an operation was necessary in order to relieve the plaintiff from the condition he was in as the result of the overlapping of the fracture must be conceded. The surgeon who performed the operation testified that he made an incision down to the bone, and then by the use of instruments refractured it where the union had taken place, made a hole in each fragment, and inserted a silver wire, and wired the bones together so that they would remain in place and prevent overlapping until a new union was effected. Considering the pain and suffering, expense, and loss of time this operation necessarily entailed, and also the fact that there was sufficient testimony from which it could be inferred that the defendant had not exercised the degree of care the law required in treating the fracture, it could not be said that the verdict was excessive, or in any sense the result of bias or prejudice. The trial judge did not find that the award of $1,000 was excessive. He did not direct that the verdict would be set aside unless the plaintiff consented to remit the sum of $350. The reduction was voluntary on the part of the plaintiff. The testimony was sufficient to sustain the award of the jury.

Insured Failing to Give Notice Because of Information Withheld by Physician—Having More than One Disease

(National Life Insurance Co. vs. Bean (Ga.), 84 S. E. R. 152)

The Court of Appeals of Georgia affirms a judgment for plaintiff Bean on a policy of health insurance, although he failed to give the required notice of his sickness for the alleged reason that his physician had withheld from him information with regard to it. The court says that the policy provided for the payment of an indemnity for a certain period during which the insured should be disabled by various diseases, including peritonitis. The policy also contained the stipulation: "Written notice of any injury, fatal or nonfatal, or sickness covered hereunder must be given to the company . . . within twenty days from date of accident or beginning of illness on which claim is based, unless such notice may be shown not to have been reasonably possible, and failure to give such notice shall invalidate all claims under this policy." There was evidence that the plaintiff, who was so insured, was treated by a physician for malaria resulting in peritonitis, and was confined to his room and bed, and was unable to attend to any business for about thirty days; that information as to the nature of the disease or sickness from which he suffered was withheld from him by his physician until after his recovery; that he did not know that he had an attack of peritonitis, or that this was one of the diseases covered by his policy, until he recovered sufficiently to go to his place of business and examine his policy, which was deposited there, and thereafter interviewed his physician; that written notice of his illness was not given to the insurance company within twenty days from the beginning of the illness on which his claim was based, but was given within twenty days from the date when the plaintiff discovered what had been the nature of his illness. It is held that, under the evidence and the stipulation in the policy, the policy was not, as a matter of law, forfeited because of the failure to give the notice within the time limit of twenty days, but it was for the jury to say whether the plaintiff had given the required notice as soon as reasonably possible under all the facts and circumstances. Nor did the trial judge err in failing to charge the jury that, should they find that the plaintiff had more than peritonitis at the time he had it or preexisting the peritonitis, and that such other sickness was partly the cause of the plaintiff's being confined to his home, he could not recover the indemnity. The issue was: Did the plaintiff have peritonitis? And, if so, how long was he confined to his house and continuously and wholly disabled solely by that disease, and by no other disease? Seldom does one have a serious physical ailment not complicated by other diseases or physical disturbances; and if proof of a preexisting disease, or of some concurrent ailment, would prevent recovery for disability caused solely by another disease flowing therefrom and a consequence thereof, for and during the period when the last disease was the sole then existing cause of the disability of the claimant, a policy insuring one against certain specific diseases would be worse than valueless.

Damages Recoverable—Need Not Submit to Operation for Nerve Tumors—Loss of Sexual Power

(Otos vs. Great Northern Railway Co. (Minn.), 150 N. W. R. 922)

The Supreme Court of Minnesota says that it is not disposed to further disturb the amount of a verdict in the plaintiff's favor, which was reduced by the trial court from $35,000 to $30,000. The plaintiff's left leg was amputated within 2 inches of the hip joint, so close to the body that the use of an artificial leg was impossible. There was not sufficient skin to cover the stump, and scar tissue formed. Four different operations were performed for the purpose of ingrafting skin on the stump. Several more were performed to remove cinders or to open abscesses that had formed. Two nerve tumors formed on the stump, caused by the ends of the nerves being imbedded in the scar tissue. These were intensely painful to the slightest touch, and caused intense spasms of pain on pressure or movement. From some cause, perhaps because of these tumors, the plaintiff suffered intense pain in the small of the back so that he could neither sit up nor use a crutch.

The defendant contended that there was a practical way of improving the plaintiff's condition, by removing the nerve tumors by an operation, which would remove the cause of pain in the stump and in the back, and to all intents and purposes restore the plaintiff's general health. The defendant claimed that it was the plaintiff's duty to submit to such operation, or, if he chose not to do so, the injuries which might be remedied by an operation should not be considered in measuring his damages. The court, however, is of the opinion that the plaintiff was entitled to an assessment of damages based on the condition he was in at the time of the trial. A person who sustains damage at the hands of another, whether through breach of contract or through tort (wrongful act), is required to take all reasonable measures to reduce his damage, but the court cannot carry this doctrine to the extent of holding that this plaintiff, who had already submitted to an amputation which a great proportion of men do not survive, and a lot of lesser operations, was under any obligation to submit to another surgical operation of the character described in pursuit of an uncertain prospect of lessening his injury and his damage.

There was some evidence that the plaintiff's injury had caused permanent impotence, due to the interruption of the course of certain nerves. Injury of this sort is easy to feign or exaggerate and hard to disprove. Temporary loss of sexual power is the usual concomitant of almost every severe injury or illness, and cannot usually be considered as a distinct element of damage. At the same time, when there is tangible proof that by reason of direct injury to the generative organs or the nerves that prompt their action, impotence results, no good reason exists why this element may not be considered. When the proof rests on opinion evidence, it should be closely scrutinized, but it cannot, in all cases, be rejected entirely. In this case there was evidence of injury to the pudic nerve, also that every known test indicated present impotence, and expert evidence, based on this alleged organic injury, that impotence would be permanent. The court cannot say as a matter of law that this evidence should have been wholly disregarded. However, it seems to the court that this verdict could be sustained without resting largely on this claim. Aside from this element of damage, the case was in no sense parallel to those involving the mere loss of one leg.

Liability of Sanatorium for Negligence of Nurse

(Pensacola Sanitarium vs. Wilkins (Fla.), 67 So. R. 124)

The Supreme Court of Florida affirms a judgment in favor of plaintiff Wilkins for $1,000 damages for a burn on his leg caused by a hot water bottle having been left in the bed where he was a patient in the sanatorium. The court holds that, as the damages were claimed for actual negligence of a nurse who was an employee of the private corporation for profit, there was no error in excluding evidence as to the competency of the nurse, or in refusing to charge the jury as to the care used in selecting nurses at the sanatorium. In other words, where, in an action for personal injuries, the damages claimed are solely for alleged actual negligence, it is not error to exclude evidence as to the competency of the negligent employee.

Money Paid for License Fee Not Recoverable

(Longstaff vs. State (S. D.), 150 N. W. R. 1100)

The Supreme Court of South Dakota sustains a demurrer to the complaint in this action, brought by the assignee of the claim of one Doran to recover from the state $500, with interest. The court says that the complaint alleged, among other things, the conviction of Doran for the violation of the statute against practicing medicine as an itinerant physician without first having obtained a license, the imposition of sentence pursuant thereto, and his appeal therefrom. That immediately after the entry of said sentence Doran, being threatened by the State Board of Medical Examiners with further prosecutions on their complaint for past violations of said law, and being by reason of said prosecution and threats of the board unable to further practice his profession in the state as his only means of livelihood pending the appeal of said case in the Supreme Court, did pay to the state of South Dakota, namely, the board of medical examiners of said state, under and in pursuance of Chapter 176 of the session laws of 1903, under compulsion and protesting the same, $500, which was the sum in the law named and designated as the license fee of itinerant physicians. That said sum was paid to the state and its said board on the express agreement, understanding and condition that it should be held subject to the decision of the Supreme Court in said appeal, wherein it was claimed by Doran that the law requiring such payment was unconstitutional and void. That thereafter the Supreme Court, in State vs. Doran, 28 S. D. 486, held that said Chapter 176, so far as it required the payment of said license fee, was unconstitutional and void, and that the state had no power or legal right thereunder to require the payment of the same. It was contended by the plaintiff that the agreement with the board of medical examiners set forth in the complaint was valid, and that the payment of the fee by Doran was involuntary. But the court is of the opinion that the plaintiff was wrong in each of his contentions. The agreement alleged to have been made by the board of medical examiners was clearly beyond its authority. The board had no authority, express or implied, to make a binding agreement such as alleged; not only that, but it is expressly provided by law that all moneys received by the board shall be paid to the state treasurer and credited to the general fund. After the money has been so deposited, it can only be withdrawn by warrant pursuant to an appropriation.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Ninth Annual Meeting, held at Buffalo, April 27-29, 1915

The President, DR. GROVER W. WENDE, in the Chair

Intestinal Stasis

DR. ALLEN A. JONES, Buffalo: Acute stasis results only when intestinal obstruction is positive and is brought about by a pathologic state causing blocking or constriction, or by a complete intestinal paralysis from some interference with the neuromuscular function of the bowel. Chronic stasis may be caused by adhesions from localized peritonitis due to gallbladder or gallduct disease, pancreatic or retroperitoneal disease, appendicitis, diverticulitis, ulcers, carcinoma or pelvic disease, veils or membranes in the ileocecal region, intestinal displacement, atony, pressure on the intestine, hernia, cicatrices, enteroliths, foreign bodies or fecal impaction and spasm, as in dynamic ileus. Postoperative intestinal stasis may occur after extensive resections, with the vicious circle, in spreading peritonitis, after ileosigmoidostomy, from the development of kinks, in cases of paralysis of the bowel, and after cautery resections from dense adhesions surrounding pockets of pus. How does enteroptosis affect or deplete health? 1. By its toxic effects. 2. By interfering with the splanchnic circulation. 3. By exciting unhealthy conditions of the colonic mucosa. 4. By its possible effect in causing appendicitis and pelvic displacement. 5. By its drag on the mesentery, causing backache and misery. 6. By its effects on the mind, the vasomotor circulation and the whole nervous system. 7. By its induction of premature old age because of its interference with the nutrition of the heart, the arteries and body musculature.

Intestinal Prolapse and Adhesions

DR. HENRY W. BETTMANN, Cincinnati: A certain hereditary predisposition does exist. Constitutional debility and maldevelopment play important rôles. Pregnancy, emaciation and improper dress are often the deciding influences. The early symptoms are those of atonic dyspepsia, although the prolapsed viscera may functionate perfectly and all the symptoms be absent. There is nothing at all characteristic about the early symptoms. In more advanced cases, disturbances of motor functions, headache, constipation, dragging, backache and emaciation are common. The third stage is reached when the nervous system yields and a state of neurasthenia ensues. Especial attention must be paid to neurotic children, particularly to those presenting the habitus enteropticus. Physical exercises and correct gymnastics are exceedingly valuable. Dress reform, the care of convalescence, especially when emaciation is present, and the proper attention to the abdominal walls after childbirth are all of the highest importance. General hygienic measures combined with an appropriate diet are often sufficient. Many patients are made permanently neurotic by having their attention directed too persistently to the position of their abdominal organs. A well-fitting abdominal bandage is exceedingly helpful in many cases. It is certainly not indicated in every case. In the young, corrective gymnastics are to be preferred. Massage is often helpful. As to the theory of colon stasis and alimentary toxemia, it would seem to a critical mind that the burden of proof should rest strongly on those who would have us believe that toxic materials are actually absorbed in damaging quantities from the colon.

Organic Obstruction of the Ileum as a Cause of Gastric Disturbance

DR. GRAHAM CHAMBERS, Toronto: The close anatomic and physiologic relationship between the stomach and the small intestine has an important bearing on the etiology of ileal stasis, for one should expect that both viscera would be affected alike by nervous disturbances. In marked cases of ileal stasis of organic origin in the lower end of the ileum characterized by high peristalsis of the ileum and impaction of the barium in the ileum against the cecum, the latter is frequently found empty, although there is frequently barium in the splenic flexure of the colon and rectum. It would appear from this that the high peristalsis in the ileum in some way brings about excessive peristalsis with the cecum. In organic obstruction of the pylorus, in the early stage at least, the same phenomena are observed. Spasm of the pylorus is a very common cause of gastric stasis. The characteristics of the pain in the region of the stomach in ileal stasis due to organic obstruction are very variable. This is probably dependent partly on the degree of stasis and partly on the nervous state of the patient. In some cases, the time of appearing after eating and the intensity and nature resemble similar characters of the pain observed in gastric or duodenal ulcer. This feature often renders it difficult to determine whether the particular state is one of intestinal stasis alone or intestinal stasis associated with peptic ulcer. Symptoms referred to the stomach in ileal stasis of organic origin are determined to a considerable extent by the associated conditions or complications. Some of the latter are diseases of the stomach itself, such as peptic ulcer; others are diseases of the adjacent organs, such as duodenal ulcers and gallstones, which are prone to produce gastric symptoms; and others again are disturbances of the nervous system, such as neurasthenia and hysteria. Any one of these may be characterized by a group of gastric symptoms.

DISCUSSION ON PAPERS OF DRS. JONES, BETTMANN AND CHAMBERS

DR. L. T. LE WALD, New York: If one undertakes to make a roentgenologic examination of the gastro-intestinal tract, he must start at the mouth and finish at the anus, and not be satisfied by giving a bismuth injection of the colon and drawing conclusions from it. I have known of at least two cases in which the colon was not the seat of the trouble. In one case, in which an ileosigmoidostomy was done, the stomach was not examined at all; but while the patient was relieved temporarily of the gastric trouble, roentgenoscopy disclosed a serious obstruction at the outlet of the stomach. I believe a large majority of these cases have a congenital rather than an acquired element.

Dr. Robert T. Morris, New York: Dr. Jones said that most of these patients suffering from chronic intestinal stasis are amenable to medical treatment. He is quite right. There is too much surgery, but also too little surgery. Half of these patients come under the observation of internists who want to give them something. If the diagnosis in these cases is made early and proper medical treatment is resorted to promptly, very little surgery will be required.

Dr. J. T. Case, Battle Creek, Mich.: Carcinoma of the colon is found particularly in two places—in the pelvic colon and in the cecum. We also find stasis in the pelvic colon and cecum, and sometimes in the right half of the colon.

The Infected Colon and Its Surgical Therapy

Dr. John W. Draper and Dr. Jerome M. Lynch, New York: From a surgical standpoint, it is necessary to include under autointoxication not alone the lesions caused by substances formed through the vital processes of the organism, which is Coombe's conception, but also those arising from destructive infection of the bowel wall, which in a sense is not true autointoxication, but essentially a surgical disease. Surgeons can at present do no better than to find a means to prevent the absorption of the toxins from a given part of the bowel, however these poisons may have been created. Most acute and chronic purulent colonic infections are surgical from the start, and the future functional efficiency of the organ and of the individual depends on early recognition and proper treatment. Acute streptococcic embolic septic colitis, chronic torpid ulcer, slowly progressive colitis and acute diphtheroid hemorrhagic colitis yield only to surgical therapeusis. No good purpose can be served by partial removal, because the colon is, as a rule, diseased from the ileocecal valve to the anus, and no one would think of extirpation. Colonic resection, in order to succeed, must be based on surgical physiology.

What are the indications for ileostomy, what for colostomy and what for resection? Acute purulent hemorrhagic and the acute purulent inflammations of the colon differ in this respect. The first is usually a general infection of the entire colon and rectum, ending in death under ordinary treatment. There is no condition more certain to yield a brilliant result if ileostomy is done in time. Appendicostomy and cecostomy will not cure. They are inadequate, and are contraindicated because unphysiologic. Another rare condition previously treated by irrigation and medication and occasionally by colostomy is multiple polyposis. Ileostomy is the proper therapy. This lesion we believe to be secondary to an infection, and the histologic findings tend to support this view. The causative relationship of infection to polyposis is further supported by the fact that after ileostomy the inflammation subsides and the tumors disappear.

The indications for laparotomy in cases not yielding to colonic vaccines and other suitable forms of medical therapeusis are chronic intractable constipation or diarrhea plus the characteristic mental lesions, together with Roentgen-ray findings and often with slow crepitation over the cecum. Resection is indicated if a nonfused, inflamed, thickened, dilated, infected cecum, often with a mesentery studded with enlarged lymphatic glands is found. As yet we have not been able to decide positively on resection until after laparotomy. As "resection" is a vague term, not indicative of any particular technic, we have suggested the term "developmental reconstruction." This embodies the resection *en masse* at the terminal ileum, appendix, and cecocolon to the region of the middle colic artery. When completed, it places the ileocolic juncture in the position occupied before birth, which is the adult position in the dog and may be termed developmental. This operation carried a mortality which is far from negligible, and has been practiced by us only on individuals who have had years of unremitting, unavailing medical treatment and who were in every way unfit. Of a series of thirteen, 23.1 per cent. died; 46.2 per cent. were cured; 23.1 per cent. improved, and 7.7 per cent. not improved. Reaction is apt to be severe in proportion to the amount of handling in the neighborhood of the second portion of the duodenum. Reaction, if present, is apt to be delayed until after the fiftieth hour. At least one among our cured cases was unquestionably saved through the administration of autogenous vaccine.

The most careful differentiation of all colonic inflammations is necessary, not alone as to character, so far as that be possible, but particularly as to distribution. Some infections are general, others segmental; the therapeusis rests largely on this, an ileostomy being indicated for the one, a colostomy or a developmental reconstruction for the other. Many segmental infections, unless surgically treated, even though relieved and apparently cured by medical treatment, invariably relapse. Cessation of symptoms for a time does not mean cure. Such infections almost invariably end in stricture, so its preventive treatment is the early recognition and surgical treatment of the cause. Whatever the nature of the primary infection, it always becomes mixed after a short time. This principle underlies the therapy of the colon just as thoroughly as it does that of the lungs.

DISCUSSION

Dr. Martin B. Tinker, Ithaca, N. Y.: The trend is decidedly against a complete colectomy among the progressive surgeons of the country. Ileosigmoidostomy has been discarded by the progressive surgeons of this country. On the other hand, there are a number of men who have taken up the less radical operations very similar in character to what has been described by Dr. Draper. Dr. W. J. Mayo recently advocated a very similar procedure and reported some satisfactory results. I believe this less radical procedure has a limited field of usefulness, and most of us have seen patients who are not likely to be permanently benefited by it. In many of these cases of colon infection, medical measures have been futile, and very little has been suggested in a surgical way. Ileostomy seems to be a simple thing to do, and I feel sure some of us will be inclined to try it in these desperate cases.

Dr. Jerome M. Lynch, New York: The early diagnosis of cancer is an extremely difficult problem in the hands of the best men. The Roentgen ray, except in the late cases, is not valuable. The diagnosis between diverticulitis and cancer is almost impossible in some cases. Indigestion is a very early symptom of cancer of the colon.

Early Recognition of Cancer of the Stomach

Dr. Julius Friedenwald, Baltimore: Unless the diagnosis of cancer is made early, surgical intervention can be only in the nature of relief and not of cure. The earlier the stage of the growth, the less positive are its manifestations. Even though the disease assumes considerable proportions, many of the important symptoms may be absent, so that at this stage a correct diagnosis may be impossible. Patients developing this disease are not, as a rule, chronic dyspeptics. The most important symptoms are anorexia, vomiting, pain, hematemesis, melena and occult blood in the stools; dysphagia; loss of flesh; the presence of a palpable tumor; dilatation of the stomach; ascites and edema of the extremities; certain roentgenologic findings and serodiagnosis by the Abderhalden method. Vomiting is of frequent occurrence in gastric cancer. Pain was present in 93.1 per cent. of 1,000 cases, and extended more or less over the entire abdomen. Hematemesis occurred in 22 per cent. of cases; in 87 per cent. the hemorrhages were multiple, and in 10 single. Melena appeared in 18 per cent. of the cases. Occult blood in the stools was present in 64.2 per cent. Dysphagia existed in 6 per cent. of the cases. Loss of flesh is a sign of considerable value and occurred in 98 per cent. of the cases, the loss of flesh varying from 5 to 78 pounds. In only 30 per cent. could a mass be palpated in six months after the appearance of symptoms. Dilatation of the stomach occurred in 40 per cent. of the cases, and this condition, when present early, is of great diagnostic value. Ascites and edema of the extremities appeared in 21 per cent. of the cases.

What Stomach Symptoms Justify Surgical Intervention?

Dr. Martin B. Tinker, Ithaca: A reduction of the present high death rate from stomach cancer and stomach or duodenal ulcer can be accomplished only when agreement can be reached between internists and surgeons as to indications for operation. Frequently, at the onset of the trouble, the symptoms are clear and distinctive, while later the clinical picture is obscure because of the symptoms resulting from adhesions, extensive involvement of surrounding organs and impairment of general health. Common to all the chronic dyspeptic troubles, such as gallstones, appendicitis and various intra-abdominal forms of cancer, are complaints of pain, vomiting, gas and distention, burning sensations and eructation of sour or bitter material. In a number of these cases it may be possible to get the early history of pain localized in the region of the appendix or under the right costal border, more or less distinctive of appendix or bile tract involvement, while in the stomach or duodenum cases the pain is more commonly located in the epigastrium. Pain is, perhaps, the earliest and most persistent of symptoms.

Examination of the abdomen early in the disease may give valuable information. Tenderness on pressure over the ulcer, usually in the epigastrium, in the vicinity of the pylorus, when present, is very suggestive, although not nearly so constant as are the points of tenderness and pain over the appendix and gallbladder. Later on, visible peristalsis may show beginning of obstruction from developing cancer or adhesions about chronic ulcer. The cases of cancer in which definite tumor is present, Czerny many years ago pronounced inoperable; and this still holds good in the great majority of cases, but some small movable tumors are readily operable and occasionally a mass of adhesions about chronic ulcer may be mistaken for cancer and justify exploration in doubtful cases. The general appearance is also suggestive. Although there is general agreement that we cannot depend on gastric contents analysis for either a positive or a negative diagnosis, it seems to deserve a place among methods of investigation. There is a constantly growing belief in the value of roentgenologic study of the stomach. The Roentgen ray gives accurate information regarding the size, position and shape of the stomach, the acidity of peristalsis and the time of emptying.

In a series of twenty-nine personal cases in which symptoms referred to the stomach were the most prominent features, the following conditions were found: cancer of the stomach, 4; ulcer of the stomach, 2; cancer of the duodenum, third part, 1; ulcer of the duodenum, 9; perforating ulcer of the duodenum, 1; cancer of the transverse colon, near stomach, 2; chronic inflammation of the bile tract, 3; chronic appendicitis, 3; tuberculosis of the cecum, 1; movable kidney, 3. In one of the movable kidney cases the displaced kidney was adherent directly over the duodenum. While it may be impossible to arrive at a positive diagnosis in many of these cases, it is almost always possible to say that serious trouble is present inside the abdomen, and that the symptoms are of sufficient gravity to justify surgical intervention. Almost always it will be possible to determine with some degree of certainty whether the stomach and duodenum are at fault or whether the stomach symptoms are caused by lesions elsewhere in the abdomen. All modern means of diagnosis should be employed and the lesion located as definitely as possible so that in the majority of cases the operation is not really exploratory; but we may be able to attck the lesion causing the symptoms without undue handling of the intestines or manipulation inside the abdominal cavity.

DISCUSSION

Dr. L. T. Le Wald, New York: There is one important point in the diagnosis of gastric and duodenal ulcer which should be considered, and that is the question of syphilitic lesions. We have had eight cases at St. Luke's Hospital in the last two years which ordinarily would have been considered ulcer or carcinoma. Dr. Meyer reported a case in which he had resected for a supposed carcinoma at the pyloric end of the stomach. The patient succumbed to the operation. A microscopic examination showed it not to be carcinoma, but a syphilitic lesion of the stomach. In another case a fatal hemorrhage of the stomach ensued. The case was supposed to be one of ulcer, but it proved to be a syphilitic infiltration of the stomach.

Dr. Robert T. Morris, New York: During the past two months I have seen operation performed in two cases by famous surgeons for gastric symptoms warranting operation, but nothing was found. These patients continued to suffer and were examined by an ophthalmologist and found to have eye strain. One patient improved so rapidly that evidently the cause of her trouble was eye strain. While the percentage is not large, a definite percentage of cases with gastric symptoms are cases of eye muscle imbalance, and we must get negative or positive testimony in these cases.

Dr. Henry L. Elsner, Syracuse: Charges are brought against the internist that these cases do not reach the surgeon soon enough. A very important reason for not delivering these cases to our surgical friends is the fact that they do not come to us. The stomach is exceedingly tolerant. A man who has a slight indigestion does not promptly seek a physician. When these patients do come, over 90 per cent. of them already have a palpable tumor. They are easy of diagnosis. Careful examination proves that they have metastases of the glands. We do not need the Roentgen ray in such conditions.

Dr. James Pilcher, Brooklyn: Cancer of the stomach and cancer of the breast occurring in young people have a greater malignancy usually than when occurring in older people, for the reason that as a person progresses in life and reaches the age of 45, from then on the lymphatics become more or less sclerotic and do not carry metastases so fast. The older the patient is, the better chance the surgeon has for effecting a cure.

Dr. Charles G. Stockton, Buffalo: When a patient represents the features so clearly described by Dr. Elsner, he is often beyond the early stage of cancer. When a man of middle age has loss of appetite, sudden disturbance of the function of the stomach for the first time in his life, and is losing weight, I would not hesitate to say that that man should submit to an exploratory operation. I feel very often that when that condition is reached, the cancer is so far advanced that our surgical friends criticize us. I believe that adenocarcinoma starting in the submucosa goes on silently, metastases begin to develop and a state of affairs is produced which we cannot recognize definitely by the means we now have. In that class of cases, the early diagnosis of carcinoma of the stomach is an accident. Occasionally we make the diagnosis, but very often we do not.

Dr. Parker Syms, New York: The early diagnosis of carcinoma of the stomach is almost impossible, and Dr. Stockton has pointed out that it is made accidentally. The results in operating on carcinoma depend on an early attack, and if we are to assume that the early diagnosis of carcinoma of the stomach deliberately made is almost impossible, certainly deliberate surgery for the cure of this disease must fail very largely.

Dr. Allen A. Jones, Buffalo: A very useful and simple procedure in diagnosis in gastric conditions is the thread test of Einhorn.

The Rôle of the Superior Mesenteric Vessels in Abdominal Disease

Dr. J. N. Hall, Denver: I have seen several cases of marked chronic dilatation of the upper portion of the duodenum in connection with narrowing below from the pressure of the superior mesenteric vessels, but my diagnosis in these cases has generally been that of pyloric or duodenal ulcer. One such obstruction was corrected by the performance of a duodenoduodenostomy by Dr. Freeman. The exact diagnosis is less important than a realization that a mechanical type of duodenal obstruction exists, and demands surgical relief. The exact method of relief concerns the surgeon rather than the internist. The statement of Spence and Graham that possibly the cyclic vomiting of children and the so-called hysterical vomiting may at times be due to chronic gastromesenteric ileus deserves our closest attention.

Similar obstruction may occur below the duodenum, as in a case in which operation was performed by Dr. Freeman. Under my diagnosis of partial obstruction in the middle portion of the small bowel, he had a gastro-enterostomy performed for duodenal ulcer four years before. Several feet of the upper small intestine were much distended, while below a point at which the ileum was compressed under the root of the mesentery, and the superior mesenteric vessels, the intestine was empty. The bowel was practically uninjured. The anastomotic opening was patent; the induration about the duodenal ulcer had disappeared, and everything in this connection seemed entirely normal. The appendix was removed, the adhesion separated, the patient instructed to lie in the right prone position, and a normal convalescence followed.

Immunization Against Measles

Dr. Charles Herrman, New York: Infants under 5 months of age are relatively immune, and in exceptional cases in which they are infected with the disease, it appears in a mild and atypical form. One attack of measles usually protects for life. The nasal discharge contains the virus twenty-four hours before the appearance of the eruption. Having convinced myself that infants under 5 months of age are relatively immune, I obtained the consent of a mother to inoculate her infant then 4 months old. It seems logical to assume that as the infant at that age is not absolutely immune, direct inoculation will convert a temporary into a more or less permanent immunity. At no time did the child present any evidence of injury, and I then proceeded to inoculate others. The material for inoculation was obtained from otherwise healthy children, taken twenty-four hours before the eruption of the measles appears. A small quantity of the mucus from the nose is collected on swabs of cotton. Only perfectly healthy infants under 5 months of age are inoculated. The swab is applied gently to the nasal mucous membrane. Forty infants were thus inoculated. The majority showed no distinct reaction, fifteen had a slight rise of temperature, and in a few instances a small number of spots were noted on the face or body. Of the forty patients, four over 1 year of age had come in contact with cases of measles and had not contracted the disease.

Pyelitis: Its Clinical Significance

Dr. Edward J. Wynkoop, Syracuse: In girls the infection may gain entrance through the urethra more often than in boys, or it may be carried from the intestinal tract. It may occur as a complication of some other condition, or it may be an independent disease. The bladder need not necessarily be infected. The classical symptoms of chill, fever and pain in the kidneys may not be present. In relapsing cases the chill may not be repeated. In any case with irregular fever, intestinal symptoms, frequent micturition, and anemia, it is well to bear in mind the possibility of pyelitis. In examining the urine a twenty-four hour specimen only should be taken. Symptoms referable to the urinary tract and anemia should always make one suspicious of pyelitis. This is a condition more frequent than we have believed, and should be borne in mind as not every illness in children is to be attributed to the intestinal tract. In the treatment of pyelitis, I have found hexamethylenamin and potassium citrate very valuable. My preference is for the use of potassium citrate. Plenty of water and attention to hygienic rules are a great help. Vaccines have not proved as effective as we might have expected. The treatment should be persisted in as long as pus is found in the urine, even though the symptoms have disappeared.

DISCUSSION

Dr. W. L. Carr, New York: In most instances, pyelitis is an infection of the colon bacillus type; but the peculiarity of the attack requires some consideration, as it does not always seem to be associated with intestinal disturbances that attract attention, nor does it always show itself after a colitis. Many of the cases are seen after influenza, and yet cultures of the urine show pure colon infection. While there is a preponderance of cases among females, there are more cases among the males than has hitherto been supposed. As the condition in the male can hardly result from an ascending infection, it is well to study more carefully the influence of the blood-stream infection. During the acute attack I use irrigations and such laxatives as are called for. The elimination of milk from the diet, if there is constipation or foul stools, is most important, and the administration of castor oil at such a time is of unquestionable benefit.

Basal Celled Epithelioma

Dr. Robert F. Barber, Brooklyn: Of 200 specimens examined, fourteen showed epithelial pearls and only two epithelial bridges. They are said to spring from the germinal cells of the skin, and are described as having different potentials. These are called the cellular potential, evident in the various types of tumors, glandular potential, accounting for the cystic tumors, and the pigment potential manifested by the pigment in growths. The types are described as (1) simplest—a nest of cells in the derma; (2) alveolar, with a small amount of stroma; (3) scirrhous, with a large amount of stroma, and (4) adenomatous, with glands and cysts. The increase in the connective tissue is interpreted as evidence of inflammation. Previous lesions were called pimples in 44, warts in 5, and burn in 1, and the pressure of eye-glasses in 1. The frequency in these cases is 100 in women and 100 in men. The average age was 56 years. There were 2 cases in the third decade and 4 in the fourth decade. The average preoperative duration was six years, the greatest being twenty-eight years and twenty-five years, respectively, the shortest six weeks. The mean size of the lesion was 3 cm., the largest 8 cm.; the smallest under 1 cm.

Cancer of the Bladder

Dr. J. Bentley Squier, New York: Operative measures for cancer of the bladder are palliative, excision and resection. It is essential to remove at times ureteral vesical opening and internal meatus, and in the event of muscular invasion of the bladder by the tumor, to remove the glands as well. The vesical neck should not be resected. It is very difficult to diagnose cancer of the bladder through a cystoscope, and often impossible after the removal of a piece of the tumor. Fulguration is a method of treatment that should be resorted to in cases of benign growths.

Hydrocephalus: Treatment by Cisterna-Sinus Drainage

Dr. Irving S. Haynes, New York: The injection of phenolsulphonphthalein provides a means of determining something in reference to the type of case with which one is dealing and whether operation promises hope for alleviation of the condition, and also the type of operation to be performed. I have operated on twelve patients; all but two were totally blind. The only logical means of draining the cisterna is into the blood stream. This I effected by means of a silver cannula with a short and a long arm at right angles with each other. While I have been able by this method to establish drainage and in some cases to improve somewhat the contour of the child's head and to prolong life, I am by no means enthusiastic, because there seems to be little or no improvement in the mental or physical condition of these children.

DISCUSSION

Dr. G. R. Pisek, New York: There are certain types of hydrocephalus, some operable and others not. If it were possible to get the child before he is damaged mentally, or after an attack of acute meningitis when hydrocephalus develops as a complication, this operation may offer hope of accomplishing something. The technic is not simple and requires a surgeon skilled in brain surgery.

Dr. Charles W. Hennington, Rochester: The operation described by Dr. Haynes seems to be in line with what we have found in laboratory work in hydrocephalus. It seems that in this operation we have the solution of the problem as to whether or not the dura and arachnoid should be punctured from the reverse side. I agree with Dr. Pisek that if these cases are brought early for treatment and the phenolsulphonphthalein test employed to determine the type of obstruction, some good results may be obtained.

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting held April 28, 1915

The President, DR. E. E. MONTGOMERY, in the Chair

SYMPOSIUM ON EMERGENCY TREATMENT

Convulsions

DR. GEORGE E. PRICE: Convulsions divide themselves naturally into two groups: functional and organic. While the same treatment is applicable to the majority, no one treatment will apply to all. A diagnosis, or at least an approximate diagnosis is, therefore the first essential. There are certain practical aids to diagnosis which can be obtained quickly: approximate age, general appearance of the patient, character of the convulsion, presence or absence of consciousness, of distinctive odors, such as in uremia or the odor of alcoholic excess; character of the breathing, history of prior attacks, history of traumatism, overindulgence in alcohol, and the taking of poison. When called to attend an infant in convulsions, if the "pride of the family" is not already in a hot bath, the physician should at once place the child in a warm bath or pack with an ice-cap to the head. If this does not suffice, chloroform will terminate the convulsion and bring about relaxation, which allows emptying of the bowel by a simple enema. This can be followed by the rectal administration of chloral and bromid in dose suited to the age of the patient, and as soon as the child becomes conscious, a purge such as calomel, followed by castor oil or rhubarb, should be given by the mouth. The hot bath is contraindicated if the fever is high or there are signs of lung involvement. Excellent results have been reported by lumbar puncture, which has been recommended in severe cases. Holt advocates the use of oxygen, and Sanders of morphin in place of chloroform. Oxygen is not readily procured, and I should certainly hesitate to use morphin with a small child unless every other measure had failed. In the epileptic attacks there should be no difficulty in diagnosis. If the patient is in bed, the matter of treatment is simplified; if on his feet, he should be lowered quickly to the floor; this is best done by approaching the patient from the rear, which I recommend as being safer for the attendant. A pillow should be slipped under the head, the clothing loosened about the neck, and a small article, such as a brush handle, slipped between the teeth to protect the tongue. In the average attack, no other measures are as a rule necessary. It is in the rapidly recurring attacks that other measures must be resorted to, as described in the treatment for infantile spasm. In the treatment of hysterical attacks, the room should be cleared as quickly as possible. Use suggestion; assure the family in the hearing of the patient that the condition is not serious and that the convulsion will soon cease. Quiet will often abate the attack. A hypodermic of water is sometimes effective. Inhalation of amyl nitrite is of value, especially as it makes a profound mental impression. In uremic convulsions, if the temperature is high, the patient should be placed in bed, wrapped in a sheet wrung out of water at from 70 to 80 F., and this covered by a dry blanket. If the temperature is not high, we can resort at once to the hot pack at intervals, followed, if necessary, by chloroform and the other usual remedies. Morphin should not here be used. If the blood pressure is very high, nitroglycerin in 1/100-grain doses every four hours should be given. If the patient becomes cyanotic, venesection, followed by intravenous injections of normal saline, is of value. Among other forms of convulsions, we have those of tetanus and of strychnin poisoning. In tetanus, the antitetanic serum is the chief remedy; first, intraspinally; and, after the acute stage, subcutaneously. If necessary, chloroform, morphin, chloral and bromid may all be used.

Pulmonary Hemorrhage

DR. JOHN D. MCLEAN: Few pulmonary hemorrhages have a fatal termination. The patient should be in a half-reclining position to facilitate the easy expulsion of blood, and should be absolutely at rest, not even lifting the hand. A hypodermic injection of one-fourth grain of morphin quiets the heart action and calms the patient. If bleeding persists, repeat the dose in two hours. An ice-bag may be placed over the point of bleeding if known, but do not try to find it, and over the heart. One dram of the fluidextract of ergot may be given, but the dose not repeated. Cracked ice in the mouth is much to be preferred to salt, and will not tend to produce nausea. If the hemorrhage is large, salt solution by the bowels is desirable; but first decide whether the mental quiet will not be upset. After three or four days, examine the chest for lung involvement. The proper treatment at the first signs of incipient tuberculosis is more important than anything else. After all bleeding has ceased, the patient should continue to rest in bed for one week and should receive easily digested food, with the exclusion of tea, coffee and all alcoholic drinks. The bowels should be kept open with the proper laxatives.

Efficient Treatment of Urgent Cases in the Hospital Accident Ward

DR. JOHN B. ROBERTS: The administrator of anesthetics and the intern who gives first aid to injured should have had at least one year's experience in practical work, and training under a superior officer accustomed to the dangers of anesthetic agents and the surgery of accident emergencies. Burns and wounds should be sterilized, and usually are better dressed dry than wet. Patients with crushed limbs should not have a tourniquet or rubber band placed around the limb far above the injured portion, because the hemorrhage should be controlled at the region already more or less devitalized. Otherwise, the surgeon when he comes to amputate after reaction of the patient, may find gangrene of flaps occur because of unwise constriction of the limb in the effort to check hemorrhage. Gunshot wounds and abdominal injuries should not be probed, nor should enemas be given to patients with suspicious traumatisms to the abdomen, lest a ruptured intestine allow the enema to flow into the peritoneal cavity. It is possible that many fingers have been unnecessarily amputated because a young intern did not realize that a plastic operation could be used to cover bones stripped of integument. Acute abscesses and furuncles should be treated by incision to evacuate pus, but should not be plugged with gauze. Gauze does not drain pus, but becomes dry, and obstructs the opening like a cork. Therefore, it causes pain by increasing tension. Open fractures should be sterilized and treated with retentive apparatus. It is unnecessary to do spinal puncture to establish the diagnosis immediately of brain injury. Examination of the spinal fluid is frequently unnecessary, and when necessary, puncture should be done with absolute asepsis and by a trained hand, two essentials difficult to obtain in the usual accident room in charge of an inexperienced resident physician. The usual fracture of the lower end of the radius should not be treated with a splint until thorough reduction has been accomplished. Fractures of the neck of the femur should not be exposed to active manipulation in the endeavor to make a diagnosis. This is particularly true in these fractures occurring in the old, in whom impaction is frequently a blessing in disguise.

Compound Fractures

DR. GEORGE P. MULLER: Compound fractures of the skull may involve the vault or the base. Fractures of the base require no immediate treatment, except cleansing and protection of the openings leading to the cranial cavity. The ear after cleansing should be plugged with gauze. These fractures occasionally require a decompressive operation. I agree with Dr. Roberts that spinal puncture for the determination of blood in the spinal canal in such injuries is rarely necessary. In compound fractures of the vault, we usually have comminution or decompression of the fragments, and the immediate treatment differs in no way from the emergency treatment of fracture of other bones. In fractures of the lower jaw, a chin-trough and a Barton bandage and a mouth wash constitute the emergency treatment, to be followed by reduction and the use of a perfectly fitting interdental splint. In compound fractures of the long bones, we are confronted with various degrees of fracture. The most important duty of the physician first called to attend a compound fracture is simply to put a sterile dressing over the site of injury, and firmly hold it in place by a bandage. Tincture of iodin may be poured into the wound, but beyond this nothing else should be done. If shock is to be treated, the common habit of injecting strychnin is to be condemned. Morphin should be given, to be followed by heat and the head-down position, and the use of saline solution as soon as convenient. Some of these cases will come under the care of the family doctor. The patient should be anesthetized, the limb raised and the bed or table covered with the rubber sheeting, on top of which is laid a sterile sheet or towels. The entire limb is painted with tincture of iodin, and the first-aid bandage cut off and the dressing removed. The remainder of the limb is painted with iodin and the limb laid down on the sterile sheet. Foreign bodies should be removed. The wound will usually require enlarging. Small pieces of bone should be removed, but large pieces preserved. Shreds of tissue should be cut away, and the entire cavity of the wound, particularly the ends of the fragments, should be swabbed with tincture of iodin. It is essential that every open space be reached by the iodin. Provision should be made for drainage with small pieces of rubber dam. The advantage of dependent drainage should be remembered, and counter openings made where feasible. Partial closure of the wound is done, and then the fracture should be carefully and accurately reduced. The rubber dam may be removed in some cases at the end of twenty-four hours; in others it may be necessary to replace it with rubber tubes. The various fractures will be splinted in accordance with their locality. I was much impressed by a recent article advocating no splint in compound fracture of the humerus, simply slinging the wrist close up to the neck and using the weight of the elbow as an extending force during the time that daily dressings are necessary. Most compound fractures of the leg should be treated by a swinging splint, such as the Hodgson or one of its modifications. I do not like plaster of Paris as an early dressing, and never use the circular bandage unless the wound is mostly healed. If plaster of Paris is used, the cast should be covered with shellac, and after making the opening over the wound, a mixture of cotton and rubber should be packed between the plaster and the skin so as to seal off the limb from the wet dressing and discharge. It will be necessary to plate certain fractures, but that should be done only in a hospital and by one who has the proper armamentarium and technic. Drainage should be removed gradually. It is the emergency treatment that determines the amount of infection and the necessity for secondary operation.

Emergency Treatment of Ruptured Uterus and Ruptured Ectopic Pregnancy

Dr. Richard C. Norris: The obstetric emergencies—rupture of the uterus and of ectopic pregnancy—practically become a discussion of the conservative versus the radical treatment of these two conditions. Rupture of the uterus is said to occur once in from 1,000 to 4,000 labors. Untreated, the maternal mortality is 90 per cent., the infant mortality, 95 per cent. Under appropriate treatment the mortality has been reduced to 50 or 60 per cent. The violence of operative procedures when the uterus is firmly contracted, or failure to recognize an obstacle to labor, has been the cause, with one exception, of all the cases of rupture during labor that I have seen in twenty-five years of active obstetric work. When a multipara suddenly recognizes a sharp, tearing pain, and labor pains cease abruptly, accompanied by the rapid appearance of signs of hemorrhage and shock; when, after an attempt at version for a cross-birth the patient falls into collapse, the merest tyro in obstetrics should recognize at once this most serious calamity of labor. The indications are to deliver the child and control hemorrhage and prevent infection. My advice to the man of average experience with operative obstetrics is to weigh carefully the well-known danger of moving the patient to a hospital, to note the degree of shock and collapse, and if provided with the means of surgically clean work, to examine carefully to learn the location and extent of the rupture and decide whether he is capable of delivering the patient and applying the conservative treatment by tampon. This work demands the best surgical technic. Like all the emergencies in obstetrics, if the first aid fails to protect from infection, the subsequent skill called to the case may utterly fail to save the patient. Even temporary control of hemorrhage cannot be accomplished until the child is delivered. If the greater part of the fetus has escaped into the abdomen, nothing short of an abdominal operation can be considered, and treatment in the hospital offering the promptest aid is necessary. If the child is still in the uterus and the rupture has occurred during attempts at delivery, if the head is within reach, apply the forceps, perforate the skull of the dead fetus and carefully extract it. Deliver the placenta manually at once. Explore the rent carefully to avoid a complete rupture. Firmly tampon the rent after applying tincture of iodin to it; then the entire uterine cavity and vagina should be firmly plugged. If the laceration is on the anterior wall, suspect injury to the bladder. Hold the uterus anteflexed by a firm abdominal binder and pad. If the rent is on the posterior wall, retroflex the uterus and hold it thus by the pad and binder. If the bladder has been torn, introduce a self-retaining catheter. Freely stimulate the patient only after reaction has appeared, giving first and at once salt solution in moderation by hypodermoclysis and enteroclysis. The tampon in the uterine tear may remain in place not less than seventy-two hours, when it may be gently removed, and if necessary, replaced. The danger of transporting a patient with rupture of the uterus is a very grave one, and the statistics of treating incomplete rupture and small complete ruptures warrant this conservative treatment at the bedside of the patient, in clean cases treated by a clean obstetrician. Cases badly shocked show a high mortality from operation; and this conservative treatment, temporarily used, may make operation after reaction much safer in such cases. Cases that come to section may sometimes be safely treated by suture of the uterus, but usually will be more safely treated by hysterectomy, and the cervical stump should be made extraperitoneal by suture in the lower angle of the abdominal incision, if the prior handling of the case presupposes infection.

Contrasting the conservative treatment of ruptured ectopic pregnancy with the prompt surgical treatment by laparotomy, there is in my judgment less to be said in favor of the conservative treatment. A diffuse hematocele of small size that sometimes follows tubal abortion from the fifth to the seventh week in which a tubal mass cannot be felt, and the clinical signs of continued bleeding are not present, may be treated expectantly with the hope of ultimate absorption of the blood mass; but these cases are rare. Intravenous transfusion of salt solution even during transit to hospital has saved many desperate cases in my hands. A quick, clean section, exsection of the offending tube, removal of the large blood-clot by sponging, and rapid closure without drainage is the usual operation of choice. The mortality rate of ruptured ectopic pregnancy under surgical treatment varies from 3 to 4 per cent.

DISCUSSION

Dr. John C. Hirst: I think we have all seen after delivery in a rather hard long-delayed labor with or without instruments a moderate amount of postpartum hemorrhage with an immoderate amount of shock. These cases are often due to rupture and incomplete rupture of the uterus in the lower uterine segment going up behind the bladder and not through the peritoneum. The cervix is split so that you can feel the ring posteriorly and feel nothing anteriorly, and above that can be felt the contracted internal os. Here there is apt to be prolonged and fatal hemorrhage with infection of both sections of the broad ligament. A case of that kind does not, as a rule, require operation, but careful packing. Many of such cases come to us infected which could have been saved by early packing removed every twenty-four hours. Two weeks are usually sufficient to control as a case of that kind. Under such conditions I have seen two cases of rupture in the last two weeks by the immoderate use of pituitary extract in which the cervix was thought to be easily dilatable. There is a tendency to forget the expulsive action of pituitary extract, and a full dose under these circumstances is apt to produce this accident. If the symptoms of rupture justify the diagnosis of rupture before the head has passed down to the vagina, I believe such a patient is safer if moved to the hospital with the baby undelivered, as the child acts as a plug to prevent bleeding and prevents also prolapse of the intestines. In the undoubted rupture of extra-uterine pregnancy, I think we cannot emphasize too strongly the need of immediate operation in the very great majority of cases.

Dr. John M. Fisher: I am reminded of a patient with ruptured ectopic pregnancy operated on by the president of this society at the Jefferson Hospital. The woman was supposed to be in a dying condition. She was pulseless when placed on the table. She was given an intravenous injection of salt solution, and although she was gasping for breath at the time of operation, she made a rapid recovery. The case made me feel that there is no time that we may consider a patient so far gone from internal hemorrhage in ruptured ectopic gestation that operation is contraindicated. The point of importance is not the ruptured ectopic pregnancy at the time of rupture, but the making of the diagnosis after the rupture has occurred. In many cases which I have seen, diagnosis was not made previous to operation, and in reviewing the history there should have been no doubt of the condition.

1. Exclusion of Pyloric Antrum.—Bartlett has excluded the pyloric region twenty-seven times on the human subject. The first fifteen patients were operated on by transverse section of the stomach with blind closure, as first suggested by Doyen, with which no other method has been definitely proved experimentally to compare in efficiency. These experiences convinced Bartlett that the technical difficulties and dangers attendant on this procedure warranted experiments, looking toward a simpler and safer method which could guarantee the same result. The details of his experiments are given at length.

2. Gastric Headaches.—Cheney calls attention to headaches due to disturbance of the stomach; to the fact that they are not an infrequent occurrence; that they present characteristics which fairly well identify them; that it is possible by stomach investigation in these cases to prove the existence of gastric disorder, as well as by other examinations to exclude disease elsewhere; and that the headaches can be made to disappear by therapy directed to the underlying gastric disturbance. The headaches due to gastric disease are usually periodic. They repeat themselves throughout months or years. They may occur but once in a month, or once or several times in a week. Over certain periods they may become practically constant, during which periods headache is never entirely absent, though worse or better at certain times in the day. But the most common story is of sudden unexpected attacks of pain in the head, coming after days or weeks of good health. Such headaches, Cheney points out, are of variable duration, but rarely last over twenty-four hours. The patient wakens with the pain in the morning, and it grows more intense as the day goes on; or it may come on in the evening, persist during the night, and pass off after the patient rises. These headaches may be so severe and prostrating as to incapacitate the sufferer for any kind of work while they last; but more often they are not so violent as to prevent the patient from going about his usual occupation, even though he feels miserable and unfit. Sometimes nausea and vomiting accompany the pain, giving rise to the popular term "sick headaches"; but in other cases there may be no disturbance whatever of the stomach to make the digestive organs even suspected. The attack results in no disturbance of health, unless it be a sense of soreness over the scalp at the site of previous pain and a feeling of mental unclearness and confusion; but these sensations are transient and the paroxysm is usually followed by complete restoration to normal. Repetition of these attacks may go on indefinitely before the real cause is discovered.

The most common type of pain is hemicrania, though not always on the same side. The pain is described as boring in character, through one eye or temple; or it may be the entire half of the head, even back to the base and the nape of the neck, that aches and throbs while the opposite side is entirely free from discomfort and as clear as ever. But this one-sided headache is caused frequently by the autointoxication of chronic intestinal stasis; it is the characteristic type of the paroxysm known as migraine; and it sometimes occurs as a manifestation of uremia. On the other hand the headache of gastric origin often involves the whole forehead and vertex with a throbbing distention and fulness, not limited to any one area; so that it becomes absolutely impossible to construct any diagnostic chart of headaches, as has been attempted, in which certain locations of pain serve to determine infallibly the diseased organ giving rise to the pain.

In the diagnosis of gastric headaches, the history makes one only suspect, the gastric analysis makes one reasonably certain; but only after elimination of all other possible causes can this one be accepted as the basis for therapy. Laxatives alone do not remove the symptoms; a proper diet seems the essential feature in treatment, the determination of what is proper depending on investigation of the gastric functions. This arrangement of dietary with other measures to overcome gastric atony and faulty secretion are often sufficient to regulate the bowels without the addition of laxatives.

3. Use of Dahlia in Infections.—Ruhräh says that a saturated (about 4 per cent. solution) can be applied to the mucous membranes of the throat or in fact other parts of the body without producing either pain or subsequent irritation. The drug seems to penetrate only to short distances and for the deeper seated affections has no value, but for superficial involvement of the mucous membranes whether the infection is due to streptococcus or to other organisms the effect is quite striking. In some cases but little effect is noted, it is true, but in others there is marked lessening of the intensity of the inflammation and coincidently a marked lessening of the constitutional symptoms. It has the advantage over other applications in that it is not painful, does not produce irritation and is markedly antiseptic. The only disadvantage is the color, which will stain fabrics with which it comes in contact, although most of these stains can be removed if the garment is immediately washed out in cold water. For ulcerations about the mouth it may be used either by applying a saturated solution or a mouth wash varying in strength from 1:1,000 or 1:10,000 may be used. The stronger solutions need not be used very frequently. The dahlia not only kills the offending organism but it has a marked stimulating effect on the healing. Externally on skin surfaces the drug may be used with marked benefit, particularly on ulcerations.

Ruhräh has used it with remarkable benefit on vaccinations which were slow in healing, and on other abraded surfaces, especially those which are infected.

5. **Generalized Telangiectasia with Syphilis.**—Cardiovascular degenerative conditions, among which syphilis is most conspicuous in Stokes' opinion appears to stand in etiologic relation to a considerable percentage of the obscure dermatoses heretofore grouped under the meaningless terms "essential," "idiopathic," and "primary" telangiectasia. The conception of a low-grade inflammation due to definite etiologic factors, such as syphilis, lead, alcohol, hyperthyroidism, etc., forms a more substantial starting point for further study than relatively intangible angioneurotic theories of the etiology of generalized telangiectases. Much of the existing confusion in the classification of telangiectatic cutaneous lesions is ascribed to over reliance on purely clinical data, whose value as exclusive criteria in these cases is open to grave doubt.

6. **Strychnin in Broken Cardiac Compensation.**—Newburgh states positively that neither pharmacologic nor clinical evidence justifies the use of strychnin in the treatment of acute or chronic heart failure.

7. **Multiple Neuritis and Typhoid.**—Claytor collected from the literature twenty-five cases which are sufficiently fully described to be of value, which, with his own, make a series of twenty-six. Symptoms of the condition were recognized during the course of the fever in 14 instances; after the fever had subsided, in 12. The earliest was the second week of fever. It is impossible from the data to say what the longest period after apparent complete recovery at which the symptoms of neuritis first appeared, but usually it was a few days to a week after the temperature had become normal. Pain was present 17 times, absent 9 times. There was altered sensation in 19, no change in 4, and no mention of this condition was made in 3 instances. Paralysis was noted 25 times; in one case it was not mentioned. The reflexes were lost in 9, exaggerated in 4, diminished in 2, normal in 1, and not noted in 1. There were no contractures in 20, while in 6 they were noted. The cranial nerves were involved in 7, not affected in 19; the spinal in 24, not so in 2, while both were affected in 5 cases. Fourteen cases showed atrophy, 2 none; in 10 there was no mention made of the condition. The duration varied from three months to fourteen in which complete recovery occurred. Unqualified recovery took place in 11, improvement in 7, death in 2, and the result was not given in 6 cases. It must be remembered, however, that many of these reports were probably made before the final result was known, and it seems likely that quite a fair proportion of those recorded as improved ultimately recovered.

30 Distension of Lungs; Its Effect on Respiration in Man and in Normal and Vagotomized Dogs. W. M. Boothby and F. B. Berry, Boston.

13. **Relation of Nodal Tissue to Cardiac Inhibition.**—This work is offered by the authors as leading confirmatory evidence to the hypothesis of chronotropic vagus action previously put forward, namely, that the vagus produces its chronotropic effect on the heart by local depression of automaticity in the nodal tissues, causing the seat of impulse initiation to undergo progressive shifting to regions of lower automaticity.

15. **Experimental Edema in Frogs.**—From the experiments described by Moore it seems clear that, in the normal frog, the water which is being continually absorbed through the skin is removed by the lymphatics and veins. When a limb is completely ligated, liquid rapidly accumulates under the ligature. This liquid is composed of transudate and of water absorbed through the skin by osmosis. Removal of the superfluous liquid is prevented because both veins and lymphatics are closed. The lymph therefore tends to become more and more dilute and the muscle correspondingly swollen with the continued absorption of water. In short, the phenomena of edema develop below a complete ligature because lymph and tissue take up water osmotically, and the avenues for its removal are blocked. In the case of edema produced by a lymphatic ligature, the lymph formed in the normal fashion is retained while the absorbed water passes into the capillaries and is removed.

17. **Cardiac Inhibition During Vomiting.**—It appears from Miller's experiments that in the dog the vomiting center when active is able to influence the cardio-inhibitory center in a powerful manner. The fall in blood pressure during vomiting in the dog, while, no doubt, in part produced by the factors effective in the cat, is materially increased by cardiac inhibition.

23. **Gastric Hunger Contractions.**—According to Patterson the variations in the gastric hunger contractions are dependent on two factors, namely: The actual age of the stomach and the rate of metabolism of the animal. The latter seems to be of the greater importance in determining the activity of the gastric motor mechanism.

24. **Diurnal Variations in Arterial Blood Pressure.**—Weysse and Lutz found that a rise of maximum pressure averaging 8 mm. Hg occurs immediately on the ingestion of food. A gradual fall then takes place until the beginning of the next meal. There is also a slight general rise of the maximum pressure during the day. The average maximum blood pressure for healthy young men in the neighborhood of 20 years of age is 120 mm. Hg. This pressure obtains commonly one hour after meals. The higher maximum pressures occur immediately after meals, and the lower, as a rule, immediately before meals. The range of maximum pressure varies considerably in different individuals, but the highest and lowest maximum pressures are practically equidistant from the average pressure of any one individual. The minimum blood pressure is very uniform throughout the day, and is little affected by the ingestion and digestion of meals. When it is affected a rise or a fall may take place. There is a tendency for a slight general lowering of the minimum pressure throughout the day. The average minimum blood pressure for healthy young men in the neighborhood of 20 years of age is 85 mm. Hg. Thus the authors get an average pulse pressure of 35 mm. Hg. Pulse pressure, pulse rate and the relative velocity of the blood flow are increased immediately on the ingestion of meals. They attain the maximum, as a rule, in half an hour, and then decline slowly until the next meal. There is a general increase in each throughout the day. The average pulse rate in the authors' investigations proved to be 72 beats per minute.

26. **Analysis of Nitrous Oxid.**—The details are given by Boothby and Sandiford of analysis of nitrous oxid by the method of combusting with hydrogen with the use of a modified Haldane apparatus.

27. **Effect of Work on Hemoglobin and Red Cells.**—Experimental data are given by Boothby and Berry showing that the percentage of hemoglobin and the number of red blood corpuscles, and therefore the oxygen carrying capacity of a unit volume of blood, are increased under conditions of work, causing an appreciable amount of perspiration. If no perspiration occurs there is no such increase.

28. **Circulation Rate in Man.**—A series of sixty-one determinations of the blood flow in one subject at rest and at various degrees of work are reported by Boothby. It is shown that the circulation rate increases proportionately with the oxygen consumption in a manner corresponding to the increase in the total ventilation. It is suggested that the main controlling factor in the regulation of the circulation rate is the hydrogen-ion concentration of the arterial blood and that this regulation is one of great delicacy. By comparing the increase in the circulation rate with the increase in the total ventilation, Boothby was able to estimate that on the subject studied an increase in the blood flow of 3.3 liters per minute, which is a doubling of the circulation rate, is caused by a rise in the total acidity of the blood corresponding to 2.0 mm. of carbon dioxid. This figure would correspond to a rise in the hydrogen-ion concentration of the arterial blood of about 0.013×10^{-7}.

41. **Bladder Ulcer in Women.**—In the eight cases cited by Hunner the ulcers were all found in the vertex or summit of the free portion of the bladder; this being one important distinction in comparing the simple solitary ulcer of Fenwick which is found on the base or fixed portion of the bladder. In three of the cases the ulcer was well forward, just back of the symphysis; in four, it was in the summit, with a tendency in three of them to occupy the posterior pole region, while in one case there was an ulcer area near the posterior pole, and another on the left anterior wall immediately back of the symphysis. A chief characteristic of these ulcers is the extremely slight mucous membrane change found in certain periods of the ulcer.

The ulcer area may easily be overlooked and the attention may first be arrested by an area of dead white scar tissue. In the neighborhood of this scar-looking area, one sees one or more areas of hyperemia which, on being touched with a dry cotton pledget, or with the end of the speculum, bleed and first show their character as ulcers. In other cases, or perhaps at subsequent examination on the same case, the ulcer may be well defined as a deeply red area with granulating base and with congested vessels surrounding the area. In none of these cases has an individual ulcer area been more than a half centimeter in diameter, although two or three such ulcers have at times been grouped in a larger inflammatory area.

64. **Aplastic Anemia of Benzol Poisoning.**—Hurwitz and Drinker found that subcutaneous injections of benzol in rabbits produce marked destructive changes in the hematopoietic organs, especially in the myeloid tissue. Benzol poisoning registers a change not only in the formed elements of the blood, but also in the factors of coagulation. The circulating prothrombin is considerably reduced in amount and in most instances animals in which such a diminution occurs show aplasia of the bone marrow. The association of extreme aplasia of the marrow without a fatal diminution in the circulating prothrombin suggests one of two possibilities; either other tissues and organs in addition to the bone marrow are concerned with prothrombin formation; or a minimum amount of myeloid tissue suffices to maintain the quality of prothrombin above a dangerous level. The myeloid tissue plays no part in the production of antithrombin. Bone marrow activity is not essential for the production of fibrinogen.

67. **Fibrous Tissue in Adult Frog Tissue Cultures.**—In living cultures of various kinds of adult frog tissues, which have been made according to the hanging-drop method, Baitsell has seen in many cases, a transformation of the plasma clot by which it becomes entirely changed from a typical fibrin net both in appearance and structure. The changes in the fibrin net generally begin when the culture is from two to three days old. During these changes it appears that the elements of the fibrin net fuse or consolidate, and as a result a great number of fine wavy fibrils are formed which unite to form wavy bundles of fibers, and these freely intertwine and anastomose as they ramify through the area of the plasma clot.

Experiments show that the fibers which are formed are not outgrowths of the imbedded tissue. Also they are not formed by an intracellular action, but arise directly by a transformation of the fibrin elements of the plasma clot. The transformation of the fibrin net will not occur unless it has come under the influence of living tissues or of living isolated cells. However, mechanical means, such as exerting tension on the clot with needles, may hasten the formation of the fibers. It is believed by Baitsell that such a reaction must play an important part in wound healing. A study of the relation between connective tissue fibers formed in wound healing and in embryonic development to the fibers formed in the plasma clot is being made by Baitsell and the results will be published later.

68. **Nature of Anaphylatoxin.**—The union of fresh serum of pregnant or immunized animals with the corresponding boiled protein (substratum) is accompanied by the formation of poisonous substances. The poison originates from the serum as a result of its autodigestion and not from the substratum. The process of autodigestion may be determined by the specific or nonspecific removal of the antitrypsin of the serum. The poisons originating from the serum are toxic only for homologous animals. The autodigestion of the serum, if allowed to proceed far enough may go beyond the toxic stage. The biologic properties of these poisons indicate their close similarity to the anaphylatoxin and suggest to Bronfenbrenner that the anaphylatoxin of Friedberger is a product of the autodigestion of serum and not of the protein outside of the serum.

69. **Distribution of Diphtheroids.**—Diphtheroids are widely distributed in nature. They are present in the air, on the body surface, and at times through contamination or are indigenous in the deeper tissues. Harris and Wade are of the opinion that diphtheroids constitute a broader field of saprophytism than is generally appreciated. While some strains may represent pathogens, their aggregate is patently not of the disease-producing variety. Diphtheroids can be cultivated from various pathologic tissues to which they bear no etiologic relation, such as lesions of tuberculosis, leprosy, blastomycosis, tertiary, syphilis and tumors of various types.

70. **Diffusion of Poliomyelitic Virus.**—According to Flexner and Amoss the ordinary virus of poliomyelitis present in aseptically removed brain tissue of paralyzed monkeys survives in an ascitic fluid kidney medium at the temperature of 37 C. for a period of at least twenty, but not thirty days. Under the conditions of moderate anaerobiosis, the minute micro-organism cultivated from poliomyelitic tissues tends not to develop in cultures from the brain tissue; hence its presence does not complicate the survival test. The diffusion of the ordinary poliomyelitic virus from a noncomminuted fragment of brain tissue into a surrounding medium of ascitic fluid is so slight as not to be detectable by inoculation experiments conducted with usual quantities of the fluid. The specific effects of the micro-organism cultivated from poliomyelitic tissues are not caused by an admixture in the cultures of the ordinary virus of poliomyelitis; hence they must be caused by the pathogenic action of the micro-organism itself. The minute micro-organism is therefore regarded by the authors as the specific microbic cause of epidemic poliomyelitis.

93. **Propagation of Pure Vaccine Virus.**—Noguchi has succeeded in propagating in the testicles of the rabbit and calf pure vaccine virus which is absolutely free of bacteria and preserves its virulence undiminished.

94. **Chronic Dilatation of Stomach.**—Chronic atonic dilatation, etiologically and therapeutically considered, Barber states, is a problem in pathologic physiology. Most cases are amenable to medical treatment. Many are relieved by suspensions. Of both of these classes many are entirely correctable physiologically by carefully planned gastro-enterostomies. The position of the stoma is vitally important and depends on the following: (*a*) For normal or hypertrophied stomachs the pylorus is the most efficient outlet. (*b*) For normal or hypertrophied stomachs the nearer the artificial stoma corresponds with the physiologic point of outlet the greater is the efficiency. (*c*) For "moderately" atonic stomachs or stomachs with 50 per cent. impaired prostaltic power, the efficiency of the stoma is probably greatest in the pyloric antrum, while (*d*) for the markedly atonic stomachs, with pronounced muscular insufficiency, the pendant stoma seems to date most efficient.

123. **Crises in Tabes.**—The gastric and pain crises of tabes are regarded by Byrne as being primarily the result of a banking of potential in the neurons distal to the lesion, namely, in the ganglion cells. This banking of potential goes on with greater or less rapidity, depending on the activity of the metabolic processes, the character of the food, mode of life, atmospheric conditions, the degree of completeness of the block in conduction at the site of the lesions, etc., until the obstruction is no longer able to prevent the passage of impulses inward toward the cord. Then individual neurons, one or any number at a time, commence discharging, and impulses reach the brain, causing pains referred to the peripheral areas of distribution supplied by the discharging neurons. In the case of the vagal and glossopharyngeal neurons the afferent impulses impinge with greatest effect on the vomiting center, causing nausea, vomiting, and the distress that accompanies them. After repeated successive discharges the cell bodies become fatigued, the potential falls below the point necessary to force a passage at the site of the conduction block, and the attack ceases for a time.

As all the neurons, however, do not discharge simultaneously, since some gather or retain their potential while others are losing it, the attacks of gastric or pain crises do not pass off immediately, except in cases in which attacks of gastric crises are temporarily aborted by such agents as morphin, pilocarpin, apomorphin, eserin, etc., and here the neurons are, to a greater or less extent discharged simultaneously soon after the administration of the drug, so that it takes some time, varying from two to forty-eight hours, before the neurons can gather sufficient potential to force the block again. In cases in which the attack has lasted some time, and in some instances in which only a certain limited group of neurons are fully, or almost fully and equally charged, the administration of morphin or of sodium salts *may discharge the accumulated potential so effectively* that the regathering of potential may take a long time. In such cases one administration of a remedy may permanently abort an attack. In reality, however, remedies seldom cause complete suspension of the attack, but merely affect the simultaneous discharge of those neurons in which the potential is at, or near the point of spontaneous discharge. The attack really comes to an end only when the potential in all the ganglion cells has become so reduced that it will take a period of some length before any of the neurons can acquire sufficient potential to force the block. The duration of an attack of gastric or pain crises depends, therefore, rather on the simultaneity and equality of accumulation of potential rather than on the number of neurons involved. General exhaustion and fatigue of the body as a whole, as well as starvation, also aid in the spontaneous termination of an attack by preventing rapid reaccumulation of potential.

131. **Radical Cure of Errors of Refraction.**—Animal experiments made by Bates demonstrate: 1. The lens is not a factor in the production of accommodation. 2. Hypermetropic refraction is always produced by a strain of two or more of the recti by electrical stimulation or advancement, and is always prevented by relaxation of these muscles by tenotomy. 3. Myopic refraction is always produced by a strain of two obliques and is always prevented by relaxation of these muscles by tenotomy. 4. Atropin prevents, when injected deep into the orbit, the experimental production of errors of refraction. 5. The cause of all errors of refraction is a strain to see. The cure is accomplished by relaxation. Relaxation is secured by central fixation. Central fixation is obtained by eye training with the aid of the Snellen test card at 20 feet and by alternately practicing central fixation with a dot or a fine point at 20 inches or nearer. After central fixation is obtained, all errors of refraction are cured.

133. **Angina Pectoris Successfully Treated.**—Tousey cites a case of *angina pectoris successfully treated by high frequency* currents from ultraviolet ray vacuum electrodes and by vibration.

12 *Right Scrotal Fecal Fistula (Hernia). W. Vost.

11. **Iodin and Vaccination.**—Iodin was recently extolled as a *preliminary disinfectant of the skin in* vaccination. Some experiments were therefore carried out under Scott's direction in the ordinary course of preparing calf vaccine at the Shillong vaccine depot. Among the calves being vaccinated

one was occasionally taken at random and prepared with iodin instead of by the usual method of cleansing the skin. Each iodin calf was thus vaccinated along with one or more others, with the same lymph and under the same conditions. The average yield of the iodin calves was 7.7 gm. and of the others 26.6 gm. Of the iodin calves, two developed so few vesicles that no useful amount of vesicular material could be removed. The other ten yielded from 2.0 to 25.5 gm. Of the 47 control calves, one yielded none and the remainder from 9.5 to 62.8 gm.

It was plain that iodin as used in this experiment seriously interfered with the development of vesicles. This was obvious to the eye without any calculation of the weight of lymph yielded. Instead of the usual thick crop, only a few scattered vesicles formed on the scarified area. The difference lay in the number of vesicles which developed and not in their size or quality. Those which did form were normal in appearance. In none of the iodin calves did vaccination actually fail altogether, but the success rate per puncture was reduced to about 25 per cent. instead of the usual 80 to 90 per cent. Only two of the iodin calves yielded anything like a good crop of vesicles.

12. **Right Scrotal Fecal Fistula.**—This was an ordinary case of reducible scrotal hernia of two years' duration in a boy of 12. Nearly a month and a half before the operation by Vost the hernia became swollen, irreducible and extremely painful, and the parents thought an abscess was forming and treated it locally for the same. Then it burst, and left a fistulous opening through which fecal matter began to pour out. The boy's general health was fairly good and he was passing feces both through the anus and scrotal fistula. The operation was successful. The opening in the bowel was closed and a Bassini operation for hernia was done.

13. **Significance of Parametrium.**—This tissue, according to Moritz, forms the vascular pedicle of the pelvic viscera. In it the vessels, nerves and lymphatics of the pelvis take their course. Its arrangement is similar to that of all mesenteries. By means of the sheaths covering these structures they are enabled to adapt themselves to the everchanging directions and dimensions of the pelvic viscera. The viscera themselves are further enabled to do this without undergoing any danger of interference with their blood supply. The densest part of this tissue is situated around the cervix uteri, and therefore that is the most fixed point of the uterus. The chief blood supply to the uterus lies just below this area. The result is that the uterus is enabled to undergo the remarkable physiologic changes to which it is subject without interference with its vascular supply.

The retroperitoneal pelvic connective tissues have been evolved in man, simultaneously with other modifications, on the assumption of the erect attitude. An examination of these tissues in lower animals (rabbits, cats, hedgehogs) shows that they are devoid of smooth muscle fibers, consisting only of a loose reticular tissue with large spaces filled with fat. The tailed monkeys possess a connective tissue which is still poor in smooth muscle and supporting elements but these are present in larger amounts than in the connective tissues of quadrupeds. The pelvic connective tissues of the anthropoid apes are exceedingly rich in smooth muscle and supporting tissue. The higher up we go in the scale the richer this tissue becomes in smooth muscle and the better it thus is adapted to the mechanical duty of keeping the pelvic viscera in position.

It is also worthy of note that the chief supporting elements of the tissue are developed conversely as the pelvic floor becomes more sphincteric in its action, and is less used for the purposes of movements of the tail. Also that these tissues become of a more highly specialized nature and assume more important functions with regard to the maintenance of the position of the pelvic viscera as the erect attitude is developed. It is worthy of note that the position of the uterus as regards anteversion or retroversion is also determined by the state of the parametrium to a considerable extent. A diseased parametrium, namely, a parametrium that has lost its tone or is poor in smooth muscle, in spite of the presence of round ligaments predisposes to retroversion. If a model of a uterus be fixed round its cervical segment by numerous strands of elastic, all having as near as possible the same tension as in a pelvis in the erect attitude, the model takes up a position of anteversion. Different areas of the elastic strands being loosed causes the model womb to assume different displacements. A strong contraction of the anterior strands will cause acute anteversion just as a slackening of this group of elastic or a pull of the posterior bands will cause retroversion. The effect of periodic changes in the sizes of the rectum and bladder will not lessen to any extent the value of this experiment. The important part this tissue plays in keeping the uterus in its normal position, therefore, is seen, and one realizes why retroversions are so common in cases of prolapse.

The structure of the connective tissue, namely, the extensible vessels, strengthened by elastic masses of smooth muscle, allows all the changes of pregnancy, of full and collapsed bladder and of rectum, etc., to take place without any vascular interference with the normal state of these tissues and without vascular disturbances.

16. **Coxalgic Pelvis.**—Five cases are cited by Briggs, all with lateral tilting of the pelvis. In each the left half of the pelvis, the diseased side, was raised. In four the right occipito-anterior and in one the left occipito-anterior were recorded as the positions of the vertex presentations. Natural delivery was accomplished in two, forceps were used in one, induction in one, craniotomy in one. Briggs believes that the conclusion is inevitable that the diseased side is raised and that the mechanism of labor is thereby favorably influenced in the moderately contracted coxalgic pelvis.

17. **Etiology and Treatment of Hyperemesis.**—Tweedy directs attention to the importance of the following clinical facts: 1. Food irritation is not a factor in increasing symptoms of toxemia of pregnancy, for croton oil has no tendency to aggravate symptoms. 2. While toxemic exacerbations may possibly arise from absorption of intestinal ferment, in practice this is found to be the exception rather than the rule, for violent vomiting may be induced or eclamptic seizures started in a few minutes after milk has been given, and before it could by any possibility have undergone fermentative change. The conclusion is forced on Tweedy that absorption of food particles during the earliest stages of their digestion are the responsible agents in hyperemesis and eclampsia.

Sterile milk or other foodstuffs, if injected directly repeatedly into the blood, is apt to exercise a poisonous effect. It is said that this poisonous effect is due to an absence of specific antibodies, for those present in the blood are incapable of rendering harmless the food particles until they have been modified by first passing through the mucous surfaces of stomach or intestines. In early pregnancy a foreign albumin appears in the blood and Tweedy suggests that the normal food antibodies are interfered with thereby. Thus the early sickness of pregnancy becomes understandable; it may be considered Nature's effort to reject food incapable of proper neutralization. It is also probably eliminatory in its effects, for its occurrence in the early morning will remove from the system the digestive excesses of the previous day. When it fails to do this, thoroughly toxemic symptoms arise. In most instances tolerance to food is eventually established, but the extent of the failure of the food particle to unite with its antibody is the measure of the severity of the toxemia. The fact that kidney inflammation is rarely seen in the early months of pregnancy may be due to the efficient eliminatory action of morning vomiting. In the worst cases of hyperemesis the alarmed stomach fails to discriminate between harmful and harmless stimuli and endeavors to reject everything; even the presence of spring water can no longer be borne, and, indeed retching can be induced by mere suggestion.

In one case of hyperemesis Tweedy tried the effect of giving olive oil before food was taken. The treatment was based on the popular belief that oil taken before a meal will prevent the most unwholesome banquet and the worst wines from disagreeing; it is supposed to do so by preventing or at least lessening the rate of absorption. The patient aborted before any data could be obtained in respect to efficiency of the method. She is now again pregnant, and in no way suffers from untoward symptoms. She attributes her immunity to the taking of petroleum in the early morning, and declares if she omits to do so vomiting recurs.

Sei-I-Kwai Medical Journal, Tokyo

January, XXXIV, No. 1, pp. 1-4

27 Pharmacologic and Chemical Study of Earth Worm. R. Mizoguchi.
28 *Experimental Study of Thyrotoxic Symptoms. T. Mori.
29 Observation of Kala-Azar in Chinese Child. S. Saito.
30 *Pathologic Meaning of Worms in Vermiform Appendix. Y. Matsuoka.

28. **Study of Thyrotoxic Symptoms.**—Mori produced artificially an inflammation of the thyroid in dogs and studied the subsequent symptoms. In some dogs paraffin (melting point 40 to 50 C.) was injected into the thyroid and in others after the same injection the thyroid was warmed for two to three hours, or iodid of potassium was given internally. Again, chlorid of calcium was injected into the gland instead of the paraffin. In all cases an inflammation of the thyroid with subsequent thyrotoxic symptoms was produced, and the author thinks the direct cause of the thyrotoxic symptoms was the resorption of the contents of the follicles.

30. **Pathologic Meaning of Worms in Vermiform Appendix.**—Matsuoka tried to determine whether the inflammation of the vermiform appendix can be caused by the worms which are frequently present in it, how often one meets the worms in the appendix, what changes they can produce in the tissues and what relation these changes have to the changes produced by the inflammation. He found the parasites or their eggs in 48 out of 103 removed appendixes; in 29 cases (28.27 per cent.) he found the oxyuris vermicularis and in 2 cases (1.9 per cent.) trichocephalus dispar. The oxyuris was found three times (9 per cent.) in 33 cases of acute appendicitis and twenty-six times (37.1 per cent.) in normal appendixes. Forty-five (43.7 per cent.) of the 103 removed appendixes were found to be normal. Parasites were found in 25 of these 45 cases (55.6 per cent.) and in 91.7 per cent. of these cases sent away from the surgical clinic. The 25 cases in which the parasites were found showed no signs of an inflammation although they were clinically diagnosed as appendicitis.

Matsuoka concludes, therefore, that the parasites do not cause appendicitis, although they produce symptoms which may be named appendicopathia parasitaria and which are characterized by the absence of fever and pain on pressure over the ileocecal region. The author's view is in opposition to that of Rheindorf, which accepts the causative relation between the parasite and appendicitis, and he thinks that the boring canals mentioned as of importance by Rheindorf are artificially produced slits in the tissues of the organ.

31 *Vaginal Cesarean Section. P. Bar.

February, No. 2, pp. 49-96

32 *Delivery with Patient's Pelvis Deformed from Congenital Dislocation of the Hip Joint. (Sur l'accouchement dans les bassins viciés par luxation congénitale de la hanche.) L. Péry and Balard.

31. **Conservative Vaginal Cesarean Section.**—Bar remarks that Dührssen's vaginal cesarean section has never found favor among French obstetricians, but that he, Bar, has found it of great service when conditions called for immediate evacuation of the uterus, as in case of uncontrollable vomiting, in failing compensation in heart disease, or other indications calling for prompt relief from the pregnancy. He says it is beyond question that vaginal cesarean section is much less dangerous than abrupt dilation of the cervix with the Bossi instrumental dilator, for example, which lacerates the cervix. He even prefers the Dührssen technic for cases requiring early abortion, if the cervix is narrow and not flexible. He prefers it to bougies for primiparae under these conditions. With eclampsia in an advanced pregnancy, it permits the extraction of the child when the cervix of a primipara is still long and narrow. The results are excellent in such cases unless the child is unusually large. The proper moment for it under these conditions is at the eighth month or two weeks later. Bar does not care to apply this technic in placenta praevia.

He gives fourteen large illustrations showing the various steps of vaginal cesarean section; it makes a surgical opening into the uterus under complete control, in a comparatively harmless region, leaving nothing to chance. It can be done under local or general anesthesia, as he describes in detail. He does not attempt to dilate the cervix beforehand, but leaves a small drain between the cervix and the bladder, if there is any dread of a thrombus. The tampon is withdrawn from the vagina in fifteen or twenty hours, and the sutures are treated as after any colporrhaphy. With the technic illustrated, he remarks in conclusion, the operation is easy. It is only very rarely that there is any serious hemorrhage from the wall of the uterus if the child is of medium size and the lower segment of normal configuration. He has never had hemorrhage of this kind but once, and then it was easily arrested by drawing down the cervix until the bleeding vessel was seen and the bleeding arrested with a single stitch. There is scarcely any danger of hemorrhage when the operation is done under local anesthesia plus a little epinephrin.

There is some danger of injury to the bladder; Hauch has statistics showing that this occurred in 11 out of 257 cases, Peterson, in 9 out of 267, and Dach 7 in 76 cases. Chirié has also reported a case in which a fistula into the bladder followed the falling off of an eschar. Bar has never had any trouble in this line and thinks there is little danger of injuring the bladder while it is being detached unless the plane of cleavage has been obliterated by old inflammatory processes. The special danger for the bladder and also of rupture of the peritoneal vesicovaginal pouch occurs when the fetus is being extracted with forceps.

32. **Delivery with Pelvis Deformed from Dislocation of the Hip Joint.**—The two cases reported by Péry and Balard confirm the view that in such cases it is not the limp nor the dislocation that is the greatest obstacle to normal delivery but the atrophy which results from the congenital luxation. The extreme slant of the pelvis in one case did not seem to interfere with the delivery; the head engaged spontaneously at the first labor contractions. Such a slant would be of serious import if forceps had to be used as they would have to be introduced perpendicularly. In this case expulsion proceeded spontaneously and rapidly, and this is the rule in a pelvis with luxation of the heads of both femora. In the second case the congenital dislocation of the left hip joint had entailed considerable atrophy of the limb and of that side of the pelvis, with complete ankylosis of the joint. All the measurements were larger than in the first case except the external bis-ischiac or transverse diameter; this was 2 cm.

smaller, measuring only 9 cm., evidently the result of the atrophy of the left side of the pelvis, verified by roentgenography. This was accepted as a sign that delivery could not proceed spontaneously, and the woman was artificially delivered at eight and a half months, with excellent outcome for both mother and child.

Presse Médicale, Paris

April 15, XXIII, No. 16, pp. 121-128

33 Attempts at Chemotherapy and Vaccine Therapy for Wounds in War. J. Danysz.

36 Six Months' Experience at a Clearing Hospital. G. Bergasse.
37 Open Bridge Plaster Casts. (Plâtres à anses sans armature.) E. Pouliquen.

35. **Unsuspected Arthritis after Fractures.**—Chaput states that suppuration in the nearest joint after fracture of a long bone is common, but is frequently overlooked. Any fissure in the bone is liable to permit the suppuration to extend and involve the joint. Such fissures should be sought for with special care in operating on the fracture. Certainty can be attained by *puncturing the joint and injecting enough* of a 1:1,000 solution of methylene blue to distend the synovial membrane slightly. If there is a communication with the fracture focus, the pus at this point will become tinged with blue in a few seconds. Even when the joint is opened up, it may seem sound, but arthritis should be suspected if the bones are friable and the color of the cartilage, synovial sheaths and intra-articular ligaments is not quite normal.

40 *Diphtheria and Scarlet Fever from Sociologic Standpoint. T. Benda.
41 Sphygmobolometry. (Die Sphygmobolometrie Sahli's und ihre Kontrolle.) G. Ollino.

39. **Uremia.**—Strauss remarks that the last ten or twelve years have seen considerable progress in our knowledge of retention of substances by the kidneys and of uremia in general, especially of the pseudo-uremia which does not show the high proportion of residual nitrogen in the blood that is characteristic of true uremia. He classifies pseudo-uremia as that with a tendency to convulsions and that with a tendency to stupor or delirium and high blood pressure, with or without symptoms of localized irritation or of deficit. There may also be dyspepsia and bilateral twitching, but these are never prominent in this type. In the convulsion type the seizures may be like those of epilepsy. They begin suddenly, and are most common with acute or subacute nephritis in children and youths. This type is closely analogous to puerperal eclampsia not only in the manifestations but in the lack of high residual nitrogen content. (In four cases he found only 40 to 60 mg. of residual nitrogen.) True uremia, with residual nitrogen between 120 and 150 mg. or higher, is encountered mostly with vascular nephritis, and thus occurs at all ages. The severer forms are met mostly in middle life or later, although the disease can be traced back into youth.

The residual nitrogen is thus important for the prognosis, as a high figure gives an unfavorable outlook, as a rule, other things being equal. He discusses the preferable technic for its determination in the blood and also for the urea, declaring that chemical examination of the blood serum affords the only reliable information as to maximal insufficiency of the kidneys. A host of pregnant facts are awaiting discovery, he exclaims, when physicians *take the trouble to investigate* the type of true or false uremia to which a case belongs, and discriminate more sharply. He gives a half-page table in which the clinical pictures in true uremia and in the two forms of pseudo-uremia are compared, listing sixteen groups of symptoms in each. The blood pressure in true uremia is generally increased, but it is very high in the arteriosclerosis type of pseudo-uremia and only moderately high in the other type.

40. **Diphtheria and Scarlet Fever from Sociologic Standpoint.**—Benda has been comparing the statistics for different districts in Berlin during the last three years, and discusses them from various standpoints. They show that diphtheria was more common among the poorer classes and scarlet fever among the well-to-do, proportionally. The mortality of both, however, is proportionally less among the well-to-do, but the individual predisposition is an important factor.

49 *Tendon Plastic Operation for Paralytic Talipes. (Zur Behandlung des paralytischen Klumpfusses.) H. Matti.

43. **Local Anesthetization of Abdominal Cavity.**—Adam shows that for operations on the abdomen to be possible without pain, it is necessary to anesthetize the skin, the layers of the abdominal wall, the parietal peritoneum, the mesentery and the lesser omentum. Then he discusses the innervation and the points at which conduction can be blocked, and relates his experience with operations done without pain under paravertebral blocking of nerves. This does not include his operations for appendicitis or on one kidney or breast, done under paravertebral blocking of one side only. No disagreeable by-effects were noticed except in three cases; one patient had a hysteric spasm after the first injection, and two others grew pale and the pulse ran up to 120, but all returned to normal by the end of the operation. In another group of 95 cases, operations were done on the cecum under direct local anesthesia.

To anesthetize the entire abdomen it is necessary to inject the anesthetic to block the nerves from the fifth dorsal to the third lumbar vertebrae. Three injections each are made with one introduction of the needle, pointing it in different directions. An illustration is given to show the technic on the seated patient as practiced in Dollinger's service at Budapest. The experiences with it are said to have been very encouraging. The aim is to block the nerve at the point from which it controls the largest area. The patients do not feel the depression common after general anesthesia, and vomiting is extremely rare and never protracted. There is further no tendency to postoperative dilatation of the stomach nor to aspiration pneumonia. The numerous injecting points and the large amount of the anesthetic used, from 120 to 160 c.c. of the 1 per cent. solution of novocain, are drawbacks that may be reduced with improved technic. The experiences to date, however, show that local anesthetization of the abdomen can be realized.

44. **Large Intrathoracic Goiter.**—In Jehn's five cases at Zurich the goiter removed measured 6 by 10 by 11 cm. in one case, and 7 by 13 in another. The goiters weighed from 170 to 500 gm. All the patients were immeasurably relieved *by the removal of the goiter*, but one woman succumbed three weeks later to pulmonary embolism. The tumors were so vascular that it would have been dangerous to cut into them, so they were shelled out whole. In order to do this, the manubrium was slit and it spread at once enough for the purpose. The operation was much facilitated by being done

under positive pressure in Sauerbruch's air cabinet. The operation was under local anesthesia alone in four cases.

47. **Overlapping Adhesive Plaster Dressings for War Wounds.**—Eisner has revived this old method of treating wounds. He applies it when the region is beginning to heal and the temperature is normal or only slightly above. He found the method useful in particular for extensive, shallow wounds. The best results were obtained with an adhesive plaster made with admixture of scarlet red.

49. **Tendon Plastic Operation for Talipes.**—Matti reports the success in paralytic talipes of an operation in which a strip of the tendon of the peroneus longus is slit off and utilized to provide a second attachment for the tibialis anticus on the lateral margin of the foot at the head of the fifth metatarsal bone. This does not interfere in the least with the normal dorsal extension or supination action of the tibialis anticus, but it compensates perfectly for the pronation defect and hence the abnormal lifting of the side of the foot. He refrains from using the flexor or supinator muscles of the posterior group, when only the extensor and pronator group are at fault. Some cases may require shortening of the peroneus tendon or substitution of the peroneus function by grafting a lateral flap from the tibialis anticus on the tendon of the peroneus longus in the leg. Still other cases are corrected more smoothly by dividing the tendon of the peroneus longus, drawing it out through a buttonhole back of the head of the fifth metatarsal bone and grafting it on the tendon of the tibialis anticus above the ligamentum cruciatum, after tunneling under the fascia on the dorsum of the foot. The exact technic of various measures to meet different indications is described, with illustrations of a few typical cases of paralytic talipes, a sequel of poliomyelitis or of unknown origin.

Medizinische Klinik, Berlin

April 11, XI, No. 15, pp. 413-442

56 *Treatment of Pregnancy Disturbances on Basis of Faulty Metabolism. (Zur diätetischen und medikamentösen Beeinflussung der Schwangerschaft und zur Eklampsiebehandlung.) P. Rissmann.

51. **Hygiene in the Field.**—Kuhn and Möllers describe the arrangements enforced wherever the troops are quartered, to ensure the health of the troops and of the native inhabitants. Facilities for bathing are provided in remodeled factories, etc. After bathing, the men are usually given tea. Provisions are also made for sports and outdoor games, and prizes are offered, as this is considered better in this "war of nerves" than sitting indoors when off duty.

52. **Typhus.**—Flügge relates that typhus has been contracted at the prisoners' concentration camps in Germany by twenty-three of the attendants and twelve of the physicians, and that eight of the latter have died. Better methods of warding off vermin must be devised, and he suggests, with rubber gloves, a one-piece suit covering all but the head, with adhesive plaster to close the openings at wrists and neck. Where this is not feasible, the edges can be smeared thick with Canada balsam or other sticky substance that would catch vermin like sticky fly paper. He stands on a sheet in removing the overgarment and the whole is then wrapped up and sent to be sterilized.

56. **Dietetic and Medicinal Influencing of Pregnancy Disturbances.**—Rissmann expatiates on the changes in the metabolism which regularly accompany pregnancy. About two-thirds of all pregnant women suffer more or less from them, and the condition should be regarded as pathologic as much as in a person with gout or diabetes. With these, we do not wait for serious symptoms to develop before instituting dietetic measures, and this should be the rule also in pregnancy. Meat and stimulants should be used sparingly, and the stomach should never be overloaded and no constipation allowed. By this means, supplemented with ovarian extract and salts, it is possible to tide the patient along and never let the pathologic condition get so serious as to bring on eclampsia. It is on a plane with uremia and diabetic coma to which metabolic disturbances have been leading up. Eclampsia, he declares, never occurs without warning signals: The residual nitrogen is abnormally high, there is also retention of sodium and generally also of potassium. Hence, he emphasizes, saline infusion is contraindicated; sedatives other than morphin and chloral should be given, as morphin acts on the medulla first, while chloral is dangerous for the kidneys and heart. A narcotic should be selected that raises the threshold for stimulation of the brain and blocks sensory stimuli from reaching the consciousness. Once the convulsions have developed, the uterus should be evacuated without delay. Lumbar puncture has been advocated by many clinicians in the eclamptic form of pseudo-uremia, and in true "retention uremia," plenty of water by the drop method in the rectum. Intravenous infusion of an isotonic (4.5 per cent.) solution of grape sugar after venesection aids in the lavage of the blood.

69 Efficacy of Liquid Paraffin with or Without Admixture of Iodoform in Treatment of Wounds in War. (Einfaches, erfolgreiches, im Balkankrieg erprobtes Wundbehandlungsmittel.) Chrysospathes (Athens).

58. **Serodiagnosis in Dermatology.**—Stümpke has examined the serum from 200 patients with skin disease and hundreds of controls, following Abderhalden's technic. With gonorrheal epididymitis, prostate, epididymis and testicle tissue were digested almost constantly and in some cases also seminal vesicle tissue. In psoriasis there was digestion of kidney tissue, as also in recent generalized syphilis. With the latter, liver and spleen tissue were also digested. Most of the skin affections tested also showed digestion of kidney tissue; liver tissue was acted on likewise by serum from most of the cases of toxic dermatitis.

59. **Technic for Esophagoscopy.**—Sternberg's advocacy of the prone (abdominal) position for esophagoscopy was mentioned in these columns April 24, p. 1457. He here expatiates on its advantages in permitting the free outflow of secretions, and that the patient, in this position, can hold the tube himself and aid in other ways so that no assistant is required. By introducing a stomach tube to the point of the obstruction in the esophagus, negative and positive pressure can be alternated, thus releasing and pumping out all secretions.

63. **Epinephrin in Treatment of Dysentery.**—Gröer has found that epinephrin by the mouth has a remarkable action in quieting the abdominal pain and tenesmus which torment the patient in the severer cases of dysentery. By giving the epinephrin every one or two hours it is possible to keep the patients entirely free from pain. In an experience with 300 cases he found that even enormous amounts were borne without appreciable by-effects. The same action was apparent after intramuscular injection of epinephrin, but with this the

usual effects on the heart were apparent, which was not the case when given by the mouth; only the relief from abdominal pain, nausea, and singultus was realized then. Pain in stomach or bowel of non-dysenteric origin was not affected in a number of cases. Addition of epinephrin to tepid saline for flushing the bowel also had such a remarkably favorable action that it suggests the possibility that epinephrin may have a direct neutralizing action on the dysentery toxin. His own experience and that of Marie and Kassowitz have confirmed that epinephrin has a detoxicating effect on diphtheria toxin to a certain extent.

64. **Psychic Symptoms after Wounds of the Brain.**—Poppelreuter has had thirty patients with brain wounds under his care and supervision for months, and has thus learned a number of points with regard to deficit phenomena. Among those he emphasizes is that the capacity for figures may be impaired when there is no actual aphasia. Hence testing with figures is a peculiarly delicate test for injury of the brain. In one shell wound of the left inferior occipital lobe, the man was unable to do any sums in division although no other mental disturbance was apparent. In nearly all the cases of injury of the right hemisphere there was more or less loss of memory. One medical student thus had lost all memory of the chemical formulas and prescriptions he had learned in his eight semesters. Localized injury of the brain entailed not only the specific deficit phenomena but the whole personality was essentially modified. The results of reeducation and training have been very gratifying, hemiplegics are learning to use the typewriter, and the deaf are learning lip reading, etc.

65. **Draining the Elbow.**—A bullet ploughed through the olecranon and the facilities for draining thus realized were so unusually good that Doberauer since has systematically trephined the olecranon in all cases requiring drainage of the elbow. He extols the advantages of this technic as it not only drains the joint by gravity and permits ample access but it leaves the ligament apparatus intact and avoids all danger of injury of nerves. The functional outcome was thus surprisingly perfect even when a bullet or shell had injured the bone and suppuration had followed.

67. **Abdominal Wounds.**—Perthes relates that the largest majority of the abdominal wounds in this war prove fatal within three days. About 42 per cent. succumb of those reaching the field hospital. In fully half of those leaving the field hospital alive, no viscus was injured and naturally these recover. Many of the others succumb to later complications. It is possible that better results might be obtained with operative treatment by one skilled in abdominal operations if done within twelve hours, when the general condition does not indicate irreparable lesions.

Gazzetta degli Ospedali e delle Cliniche, Milan

March 25, XXXVI, No. 24, pp. 369-384

70 Crotalin in Epilepsy; Five Cases; No Appreciable Benefit. (Sul valore curativo del veleno del crotalo nell' epilessia.) G. Corso.

April 4, No. 27, pp. 417-432

71 *Associated Lymphoid and Myeloid Proliferation. (Le linfomielosi associate.) G. Ghedini.

72 *Landau's Color Test for Syphilis. (Studio della reazione di Landau nella sifilide.) G. Cappello.

April 8, No. 28, pp. 433-448

73 Painless Delivery Under Narcophin-Scopolamin; Seven Cases. (Il parto senza dolore.) E. Curti.

71. **Combination of Lymphosis and Myelosis.**—Ghedini remarks that the association of abnormal proliferation of the lymphatics with proliferation of the blood-producing organs is not admitted by some, but he cites four typical cases to establish its possibility. One is from his own experience and one was observed by Ollino, the others by Herz and Frank. In his case the myelosis came on in the course of chronic lymphosis, in two others the two seemed to develop together, and in the fourth case the lymphosis developed during chronic myelosis. Some were of the leukemic and some of the aleukemic type.

72. **Landau's Color Test for Syphilis.**—Cappello's experience with the Landau test has been extremely favorable. The findings in 41 cases were positive in 13, dubious in 4 and negative in 24 while the parallel Wassermann was positive in 11 and negative in 26. In 27 cases (65.8 per cent.) the two tests gave concordant findings, including 8 with positive reactions. The tests gave contradictory findings in 17.3 per cent. In the 14 other cases in which there was partial disagreement, the clinical manifestations sustained the Landau findings against the Wassermann in 6 cases, and sustained the Wassermann against the Landau in 2. In 4 cases of syphilis in which vigorous treatment had been given, the Landau was still positive in 3, while only 1 responded positively to the Wassermann, indicating that the Landau is more sensitive than the other. He says he followed Landau's second technic which he cites as follows, crediting it to the *Presse Médicale*, May 2, 1914: To 0.2 c.c. of the blood serum in a test tube he adds 0.1 c.c. of the reagent, represented by a 1 per cent. solution of iodin in carbon tetrachlorid. The mixture is set aside at room temperature for four hours. With normal serum the fluid is an opaque white, while syphilitic serum is clear and transparent. Cappello made up the reagent fresh each time, with serum not over six hours old, and free from hemoglobin. The only change he made in this technic was to use *double the quantities of both serum and reagent.*

80 *Operative Treatment of Sagging Liver and Gallstones. (Epatopessia e colecistostomia contemporanee per epatoptosi totale e calcolosi.) M. Francini.

77. **Thymus Tumors.**—Roccavilla describes a unique case of a tumor in the thymus—although Claude has recently reported a case resembling it in some respects in a man of 51 with paralytic myasthenia. He was under close medical observation for eight months but never presented any symptoms of pressure in the mediastinum, and yet necropsy revealed a retrosternal encapsulated primary epithelioma starting in the thymus. It had developed mostly to the right so there was no pressure on the trachea or large vessels. In Roccavilla's case the large tumor in the thymus was of a lymphosarcomatous and endotheliomatous nature. The patient was a man of 52 with paraplegia, and he was under observation only two months before his death. He succumbed to sepsis from a decubitus. The tumor had spread in various directions but had adapted itself to conditions so there was no compression of vessels or organs enough to induce symptoms, although the bodies of the four adjoining vertebrae had softened. The details of the case and necropsy findings were published at the time, July, 1913, and have attracted considerable attention. Roccavilla replies here to a number of questions asked or points raised by others, discussing the diagnosis of thymus tumors in general.

80. **Operative Treatment of Sagging Liver and Gallstones.**—In Francini's patient the sagging liver was part of a general tendency to ptosis of the viscera that had developed after repeated pregnancies at brief intervals. After a period of mild local pains, they became intense and radiated to the shoulder. The liver was fastened in place by Jeannel's technic, after which the gallbladder was opened to remove the gallstones and the lips of the incision were sutured to the wound. By this means all danger of infecting the new supports of the liver was avoided while the gallbladder supplied additional support.

84 Echinococcus Disease in Rio. (Da presença do cysto hydatico no Rio de Janeiro.) L. Travassos and O. D'Utra.
85 *Tartar Emetic Specific Treatment for Leishmaniosis; Three Cases. O. Torres.

83. **Chorea in the Pregnant.**—Ayres emphasizes that chorea in pregnancy is probably connected with some disturbance in the ductless gland system. The mortality is always high and the prognosis grows graver when it is accompanied by mental disturbance. He proceeds to compare three cases he has encountered with the data in the literature, and gives the details of his cases. The first patient was a woman of 27 and the chorea came on with a stormy onset and coma for several hours. The choreic movements and convulsions continued a progressive course, only transiently influenced by symptomatic treatment of all kinds, including magnesium sulphate, thyroid treatment, various sedatives, neosalvarsan and lumbar puncture. Abortion was early induced but made no difference in the clinical picture, and the chorea progressed to a fatal termination. The woman had been previously healthy except for a tendency to constipation. The Wassermann was negative as likewise examination for gonococci.

The second patient, 18 years old, was also previously healthy and the pregnancy was only of one month's standing. The acute chorea proved fatal the ninth day. The necropsy findings are related in detail, but nothing was found that threw any light on the case. The third patient was 23, and she had noticed the choreic movements almost from the first after conception. At the fourth month they had become so violent she entered the hospital where the uterus was emptied after failure of all other treatment to relieve, and the chorea ceased at once. A year or two later she passed through a normal pregnancy without any return of the chorea or other mishap.

85. **Tartar Emetic in Leishmaniosis.**—Torres' three patients were men of 19, 40 and 43, and the leishmania ulcerations in the throat and nose were of several years' standing in all. A complete cure has been realized in one case under the intravenous injections of the antimony and potassium tartrate, and the others are well on the way to recovery. The first mentioned was given about forty injections, representing a total of 4.6 gm. tartar emetic. The leishman lesions in the mucous membrane are much harder to cure than those on the skin. The latter yield promptly to this treatment. It has no action on syphilis, and the measures found useful in syphilis have no effect on leishmaniosis. An interesting illustration of this, he adds, was given in a recent case of leishmaniosis in a child with inherited syphilis. The manifestations of the latter subsided under mercurial treatment, leaving the leishmaniosis unmodified, and this subsided under the tartar emetic. The solution for injection must be made up fresh and the course commenced with small tentative doses. Cautious local applications may hasten the cure.

92 *Multiple Ligation of Varicose Vein. (Behandling af Varicer paa Underekstremiteterne efter Kuzmik-Shedes' Metode.) K. Secher.
93 Chronic Nonmalignant Tumor of Salivary Gland. (Kronisk Spytkirteltumor.) H. v. Thun.

92. **Ligation Method of Treating Varices.**—Secher has applied to four patients the technic introduced by Schede and Kuzmik, and extols it as simple and free from danger, while it takes comparatively little time and the outcome is excellent and permanent. It can be applied in the home or office, and is thus particularly useful for the general practitioner. Kuzmik has reported its application in 155 cases; in most of them the varices were extremely pronounced and of long standing. Under general anesthesia a silk suture thread or catgut is passed around under the vein, without exposing the vein, and this is repeated at intervals along the vein. The ends of each thread are then tied over a roll of gauze or rubber tube, and the patient stays in bed one or two weeks. Schede applies the catgut threads at 2 cm. intervals and removes them after two or three days and lets the patient get up with a bandage the eighth day. Kuzmik uses silk, at 5 cm. intervals, and leaves the threads unmolested for twelve days.

Hygiea, Stockholm

94 *Cerebellar Symptoms in Myxedema. (Om lillhjärnssymptom vid myxödem.) M. Odin.

94. **Cerebellar Symptoms in Myxedema.**—Odin gives an illustrated description of a woman of 52, previously healthy and with healthy children, who had developed myxedema in the last ten years. The gait finally became slow and dragging, as likewise the speech, and certain groups of muscles displayed a tendency to catalepsy and other cerebellar phenomena. Under thyroid treatment of the myxedema the cerebellar ataxia and other symptoms promptly disappeared. Söderbergh has reported similar cerebellar phenomena in four cases, but Odin's was the only one in the group of five with what is called *mouvements démésurés.* All of them displayed pronounced catalepsy, contrasting curiously with the bright and intelligent mind in each case.

Nordisches medizinisches Archiv, Stockholm

103 *Stomach Disturbances in Connection with Chronic Inflammation of the Omentum. (Gastropathia epiploitica.) G. Ekehorn.

95. **Torsion of the Testicle.**—Löfberg has reported three cases compelling operative relief, but in the case related by Prag the testicle was merely untwisted back into place. The torsion must have been of 360 degrees. The young man had had a similar attack a few months before, sudden intense pain in the abdomen and scrotum coming on in the night. Just as he reached the hospital all the pain vanished, and nothing abnormal could be found. The patient has been warned to apply without delay for operative fixation if there is any further trouble in this line.

96. **Malformations of the Kidney.**—Key reviews the various types of malformations of the kidney that have been encountered, and emphasizes the necessity for bearing in mind the possibility of a deformity of the kidney.

97. **Metapneumonic Empyema.**—Borelius relates that 27 were cured by operative treatment, of the 34 cases of metapneumonic empyema in his service at Lund since 1908. In 21 cases of septic empyema, 16 were cured and 2 of 7 with

tuberculous empyema. Four recovered of the 5 in the group treated with thoracentesis alone; they left the hospital in good condition in from thirty to forty-five days. In 12 cases thoracentesis had to be supplemented by thoracotomy and 10 recovered, but this required from thirty-six to 230 days, averaging 107. The 13 who recovered out of 17 under primary thoracotomy were in the hospital from twenty-one to 120 days. In the 21 septic cases, recovery in 16 was not complete until after intervals up to 420 days, and 5 patients died. In his 8 cases of metapneumonic empyema last year, 3 were pure pneumococcus cases and some recovered after thoracentesis alone. The technic for the operation and the aftercare are important factors in the outcome and thorough and early draining is indispensable. The figures cited all testify in favor of primary thoracotomy as giving the best result on the whole.

98. **Autobone Fixation of the Spine.**—Waldenström has been applying Albee's transplant method of operative treatment of deformed spine from spondylitis, only he regards the fixation as the important point. In order to render the fixation firmer, Waldenström implants the bone in a way to take the place of the destroyed bone and support the weight of the body above. He straightens the spine first and seeks to have it and the tibia transplant fused into a solid, unbending, straight whole after the operation. He keeps the patient on his back in the same plaster bed in which the correction of the hump has been realized. Then a plaster corset is worn for two more months. Weight bearing should be very slowly and gradually permitted, not allowing strain enough to bend the bone implant. He gives the details of his operation which differs in a number of points from Albee's technic. The spine is now straight and firm in all but three of his 21 cases thus treated; in seventeen the course is complete and the results most gratifying.

100. **Transpleural Resection of Cancerous Esophagus.**—The tedious operations in the two cases were carried through successfully, but one patient succumbed to pulmonary embolism a few days later and the other to suppuration around a perforation in the esophagus. The necropsy showed that the operation itself had been a success. Bauer advocates operating as the last resort in every case. After an opening has been made into the stomach and the patient's strength brought up by good nourishment, the chest should be opened and, if there is any chance at all, the esophagus should be resected.

103. **Stomach Trouble Secondary to Chronic Inflammation of the Omentum.**—Ekehorn reports two cases and cites one published by Destot in which chronic inflammation of the omentum caused pain in the stomach region, independent of the meals, and vomiting after eating. The pains and cramps lasted about a half hour at a time and returned several times a day or with free intervals of a few days. These disturbances had dragged through several years in one case. In the second case the onset was more stormy and the troubles more serious and persistent. Immediately after eating there were stabbing pains, even after a small glass of milk. This patient was a man of 37 and operative relief was obtained after three months. There was a tender area above the umbilicus in both, but roentgenoscopy was negative and nothing was found to suggest an ulcer. In both the omentum showed signs of chronic inflammation, and both were entirely cured by resection of the omentum. The first patient, a married woman of 31, had vomited after every regular meal for eight years; there has been no vomiting since the operation, and no pains in either case. Certain signs in the second case suggested that the inflammatory process in the omentum might be traced to appendicitis, but nothing was found to explain it in the woman.

104. **Ulcer of the Lesser Curvature of the Stomach.**—Borgbjærg analyzes his experiences in 48 cases of pyloric ulcer, 13 of duodenal and 27 of ulcer in the lesser curvature, with special regard to the latter group in the total 88 cases. Thanks to roentgenoscopy, an ulcer in the lesser curvature is now readily diagnosed as a rule. In 14 cases of simple ulcer in the lesser curvature, periodical recurrence of the pains was unmistakable in 78.6 per cent., but there was no evidence of hypersecretion except in 14.3 per cent.; acidity was normal in 42.9 per cent., and below normal in 28. There was no pronounced retention of stomach content in any case, and the evacuation of the stomach was normal in 50 per cent. and only slightly retarded in 28.6 per cent. In 6 of the 14 cases there was vomiting but it occurred soon after eating and was of small amount, sometimes being only mucus. There had been hematemesis in 5 and melena in one case.

The most constant and characteristic symptom was pain in the cardia region sooner or later after eating. This pain seems to come on early when there is hypersecretion and late with subacidity. These data demonstrate that from the clinical symptoms alone it is impossible to determine the location of the ulcer or even that there is an ulcer. The disturbances were ascribed to everything but the right cause, and futile treatment had long been applied for the assumed neurasthenia, hysteria, colitis or gastroptosis. One or more of these affections may actually accompany and overshadow the ulcer. The patients grow more and more nervous as their general health is suffering from the ulceration, and the various measures applied fail to relieve their symptoms.

Localization of the pain in the lesser curvature region is instructive, as also tenderness at this point. In order to avoid suggesting this tenderness, he begins to apply pressure at a distance and gradually works up to the suspected point. Suspicious clinical findings become certainties when confirmed by the Roentgen rays. He found pronounced circumscribed pain on pressure in two-thirds of his 27 cases of ulcer in the lesser curvature, and in 71 per cent. of his 14 uncomplicated cases. This tenderness is particularly suggestive when it is to the left of the median line. In the 48 cases of pyloric ulcer, there was tenderness in 21, but always to the right of or on the median line, with one exception.

Adding his 27 cases to 27 from Pers' service, a radical operation was done in 20 of the 54, and the outcome seems to show that radical measures are more effectual while fraught with no more danger than conservative treatment. They sweep away all danger of cancer in the ulcer.

106. **Nutrient Enemas.**—Scheel tabulates the metabolic findings and other details in four out of sixteen cases thus investigated over several weeks on different types of nourishment by the rectum. The findings testify to the good absorption and utilization of suitable nutrient enemas, thus sparing the reserves in the body and supplying quite an essential part of the nourishment requirement. It was found that milk and eggs irritated the rectum and were not absorbed properly, not even when pancreas extract was given with them. The best results were obtained with meat amino-acids. The 10 gm. nitrogen were given with 50 or 75 gm. grape sugar in the course of the twenty-four hours fractioned in two or three enemas. About 250 c.c. of fluid was found the best amount for a single enema. The osmotic concentration was kept at about the same as that of the tissues, to avoid irritation. More than 25 gm. sugar should never be given at one time. He found the drop method impracticable for reasons he enumerates. The nutrient enemas were kept up for nearly three weeks. It is possible in this way to supply 400 or 600 calories daily. As the nitrogen balance is thus maintained, the reserves of fat in the body are drawn on for the balance of the calories required, and this fat loss can soon be made up again at the close of the course. All the patients had had hematemesis from a gastric ulcer. Most of the amino acids used were made in the hospital by long continued digestion of meat or milk by trypsin-erepsin.

HISTORY AND EPIDEMIOLOGY OF TYPHUS FEVER

V. C. VAUGHAN, M.D.
ANN ARBOR, MICH.

There are medical historians who find evidence of the existence of typhus fever among the ancient Hebrews and their contemporaries, but this is a matter of conjecture. While this disease has long been known as morbus pauperum associated with want and famine, we must not infer that it is the only fever which develops and thrives among the needy and in times of scarcity of food and other privations. Poverty and overcrowding favor the development and distribution of many infections. Some of the cases reported by Hippocrates in his book on epidemics are certainly suggestive of typhus. The following is the report of a case, now believed to have been typhus, made by Hippocrates, as translated by Adams:

> In Thasus the wife of Dealces, who was lodged on the plain, from sorrow was seized with an acute fever, attended with chills. From first to last she wrapped herself up in her bedclothes; still silent, she fumbled, picked, bored and gathered hairs (from the covers); tears and again laughter; no sleep; bowels irritable, but passed nothing; when directed, *drank a little; urine thin and scanty; to the touch of the* hand the fever was slight; coldness of extremities. On the ninth (day) talked much incoherently, and again became composed and silent. On the fourteenth, breathing rare, large, at intervals; and again hurried respiration. On the sixteenth, looseness of the bowels from a stimulating clyster; afterwards she passed her drink, nor could retain anything, for she was completely insensible; skin parched and tense. On the twentieth much talk and again became composed; loss of speech; respiration hurried. On the twenty-first she died. Her respiration throughout was rare and large; she was totally insensible; always wrapped up in her bedclothes; either much talk or complete silence throughout. Phrenitis.

The great Athenian pestilence so well described by Thucydides was either typhus or the pneumonic form of the plague. Livy and Tacitus tell of many epidemics in the classical period of Rome. Some of these undoubtedly were epidemics of the plague, while the descriptions of others suggest typhus. The dark ages were so overshadowed by disease and superstition that medical records of value are almost wholly wanting. In the siege of Granada in 1489 no less than 17,000 of Ferdinand's soldiers died of a fever which was designated as "Tabardillo," on account of the spots appearing on the skin. This term is still one of the Spanish names for typhus. In the sixteenth century two Italian physicians, Fracastorius of Verona and Cardanus of Pavia, described typhus fever so plainly that there can be no doubt about the disease which then prevailed. In four years (1550-1554) more than one million people in Tuscany were destroyed by typhus. Fracastorius describes the disease as "Febris pestilens," and states that it was vulgarly known as "Lenticulae" or "Puncticula." He says from the fourth to the seventh day red eruptions appear on the arms, chest, and back. They resemble flea bites, only are somewhat larger. They also resemble lentils and from this comes the popular name. The most marked symptoms mentioned are great prostration, feeble pulse, injected conjunctivae, and low muttering delirium. Some are somnolent while others are excited and wakeful, while in still others these states alternate. The disease lasted from seven to fourteen days, rarely longer. The majority of those who were bled died and a supporting treatment proved best. Cardanus and other Italian physicians stated that many of the practitioners of the time mistook this disease for measles, and Massa of Venice wrote on the distinctions between the eruptions of this disease and those of measles and smallpox. About the middle of the sixteenth century this disease was widely prevalent in France and Coyttarus of Poitiers wrote a monograph on it, under the title "De Febribus Purparatis" and somewhat later Ambrose Paré, the distinguished surgeon, wrote of "febris pestilens" which was marked by eruptions resembling the bites of fleas or bed bugs.

Morbus Hungaricus appeared in the army of Maximillian II in Hungary in 1566, and soon spread over the greater part of Europe. Sennertus and others have left descriptions of this epidemic. The skin was marked by flea-bite eruptions. Headache was intense and followed by delirium. In some, the tongue became black, parotid abscesses developed and gangrene of the limbs occurred.

Under the title, "Febris maligna puncticularis seu peticularis," Castro of Verona (1580) pictured the symptoms. The pulse is small and weak; the tongue dry and black; the face and eyes greatly congested; delirium, followed by stupor deepening into coma; parotid abscesses in some, the eruption appearing about the seventh day and the disease continuing from fourteen to twenty days. Castro says that this disease was known to the French as "La Pourpre;" to the Italians as "Petecchie;" to the Spaniards as "Tabardillo," and to the Germans as "Fleckfieber."

During the sixteenth century typhus fever was so prevalent in the jails of England that the disease spread among the court officers when prisoners were brought before them for trial. This happened repeatedly and gave to court sessions the designation of "black assizes." The first of these of which record is left occurred at Cambridge in the thirteenth year of the reign of Henry VIII (1522). The justices, bailiffs, gentlemen and other persons in court were seized with a fever which proved fatal to many. The most notable report of a "black assize" is that at Oxford in the twentieth year of the reign of Elizabeth (1577). The prisoner was Rowland Jenks, a bookbinder and a Roman Catholic, who was charged with treason and profanity of the Protestant religion. He was sentenced to lose his ears. The trial was held at Oxford Castle, July 4. Several prisoners were brought into court in the course of the trial. The chronicle states that "an infectious damp of breath" spread through the room. "Above six hundred sickened in one night; and the day after, the infectious air being carried into the next village sickened there more than an hundred more." By the twelfth of August 510 persons perished. "The infection arose from the nasty and pestilential smell of the prisoners when they came out of the jail, two or three of whom had died a few days before the assize began." The disease was marked by loss of appetite, headache, sleeplessness, loss of memory, deafness and delirium, so that the victims behaved like madmen. The Catholics saw in this the scourge of God for the unjust punishment, and the Protestants attributed it to the "diabolical machinations of the Papists."

During the Thirty Years' War (1619-1648) the whole of central Europe was desolated by war, famine and pestilence. The nature of the epidemic is plainly shown by both medical and lay writers and its ravages were portrayed in both prose and poetry. One verse of a song runs as follows:

> Per omnes
> Burgundos et quas stagnans Arar irrigat urbes
> Insolita exarsit febris, quae corpora rubris
> Inficiens maculis (triste et mirabile dictu!)
> Quarta luce frequens fato pendebat acerbo.
> Pulsus erat minimus, tremulusque soporque
> Mens vaga, visque labens; lotium crassumque rubensque
> Interdum tenuae instar aquae.

In 1658, Morton states that England was one vast hospital filled with the victims of a fever with "maculae latae et rubicundae morbillis similes in toto corpore." The great plague of London (1665) was preceded, accompanied, and followed by typhus and some of the most eminent medical men of the time, notably Sydenham, frequently confounded plague and typhus in the reports of their cases. Under the title, "Febris Petechialis vera" Hoffmann of Halle (1700) gave an excellent account of typhus and pointed out its distinction from the plague, which he designated "Febris Pestilens." The eighteenth century saw no abatement of epidemics of typhus. This disease had long afflicted Ireland under the name of "Irish ague," but it was not until 1708 that permanent records of its ravages were made. From that time on for more than a century and a half Ireland was afflicted by one epidemic after another, just as fast as new generations supplied a crop of susceptible material. The historian has no difficulty in showing that each exacerbation was coincident with a period of great want and poverty, but this was a chronic condition of the Emerald Isle during this period. The people were oppressed by their rulers, divided among themselves, held in the grossest ignorance and fed on superstition. Most of those who had enough energy emigrated to foreign lands, thus impoverishing their native land of its best blood to such an extent that it has not yet wholly recovered. An account of one epidemic of typhus in Ireland is much like all others. Nothing to eat but potatoes; and an adult would devour ten or more pounds of these tubers each day in the vain attempt to supply his body cells with the minimum amount of protein demanded. Driven by hunger to sell the cow, furniture, and even his clothing, the Irishman and his family huddled together in rags and filth, while vermin fed on their bodies and simultaneously inoculated them with typhus. Murchison says: "In Dublin, the servants of the upper classes were not allowed potatoes, and bread was portioned out to them sparingly, few persons had more than a quarten loaf in the week. The poor pawned their clothes, and even their bedding for money to purchase food, and, as a natural consequence, it was common for several members of one family to sleep in the same bed." According to O'Connell, eighty thousand Irish died in 1740-1741 of famine and spotted fever and one-fifth the population of Munster perished. Writing of a nineteenth century epidemic of typhus in Ireland, Murchison says:

> Extreme distress ensued. The four pound loaf was sold in Dublin in 1817 for 1s, 9d; and the poor throughout Ireland are described as wandering about the country gathering nettles, wild mustard, and other weeds, to satisfy the cravings of hunger. . . . The probable population of Ireland at this time was, in round numbers, six million, and the number of sick was estimated at 737,000, or at about one-eighth. In Dublin alone there were about 70,000 cases, making about one-third the inhabitants.

Of the same epidemic Carleton wrote:

> People collected at the larger dairy farms waiting for the cattle to be blooded, so that they might take home some of the blood to eat mixed with a little oatmeal. The want of fuel caused the pot to be set aside, windows and crevices to be stopped, washing of clothes and person to cease, and the inmates of a cabin to huddle together for warmth. This was far from the normal state of the cottages or even of the cabins, but cold and hunger made their inmates apathetic. Admitted later to the hospitals for fever, they were found bronzed with dirt, their hair full of vermin, their ragged clothes so foul and rotten that it was more economical to destroy them and replace them than to clean them.

The roads were filled with infected vagrants and many a poor cottier not only divided what he had in alms, but by giving shelter to the wanderer introduced the infection into his humble home, while "the dogs of the gentry kept all beggars from their gates."

The last great Irish famine (1845-1848) was the occasion for the prevalence of relapsing fever and scurvy as well as typhus fever. This scourge was foreseen in the development of the potato blight and was mitigated somewhat by the repeal of the corn laws and by a change in the navigation laws permitting the carrying of food supplies in other than British bottoms. At that time Ireland lived almost exclusively on milk and potatoes. Although it produced more than enough grain to feed itself, even in these years of the potato blight, most of this had to be sent to England to pay the rents. Years before both Malthus and Cobbett had protested against a people trying to live so largely on potatoes. The former wrote as follows:

> When the common people of a country live principally on the dearest grain, as they do in England, on wheat, they leave great resources in scarcity; and barley, oats, rye and cheap soup and potatoes all present themselves as less expensive, yet at the same time wholesome means of nourishment, but when their habitual food is the lowest in the scale, they

> appear to be wholly without resource except in the bark of trees like the poor Swedes; and a great portion of them must necessarily be starved.

After this famine the Irish ceased to rely so largely on the potato, emigration to this country and Canada greatly increased, and "the population has steadily declined and the well being of the people steadily improved."

Before dismissing the subject of Irish typhus epidemics, I wish to add a quotation from Creighton, showing that the case mortality in this disease is higher among the robust and well fed than among the weak and hungry. "There appeared to be a scale of malignity in the fevers in an inverted order of the degree of misery. The most wretched had the mildest fever, the artizan class or cottagers had typhus fatal in the usual proportion, the classes living in comfort had typhus of a very fatal kind. This experience, however strange it may seem, was reported by medical observers everywhere with remarkable unanimity. One says that six or seven of the rich died in every ten, others say one in three. Forty-eight medical men died in 1847 in Munster, most of them from fever; in Cavan County seven medical men died from fever in twelve months and three more had a narrow escape of death; two of the three physicians sent by the Board of Health to the coast of Connemara died of fever. Many Catholic priests died, as well as some of the established Church Clergy; and there were numerous fatalities of the resident gentry and among others who administered the relief. Yet a case of fever in a good home did not become a focus of contagion; the contagion came from direct contact with the crowds of starving poor, their clothes ragged and filthy, their bodies unwashed, and many of them suffering from dysentery. The greater fatality of fever among the richer classes (of course, with a much smaller number of cases) has been a commonplace in Ireland and is remarked by the best writers."

Creighton in his valuable "History of Epidemics in Britain" has shown some interesting facts concerning typhus in England during the eighteenth century. I will follow his facts but will draw my own conclusions.

During the half century from 1715 to 1765 England was most prosperous financially. Monied men built up great fortunes and the necessities of life were abundant and cheap. With two or three exceptions the harvests were rich and grain was exported in great quantity. Historians state that under the first two Georges there was general prosperity. Even Adam Smith speaks of "the peculiarly happy circumstances of the country during the reign of George II (1726-1760). Hallam speaks of this period "as the most prosperous that England had ever experienced." Lecky says:

> All the evidence we possess concurs in showing that during the first three-quarters of the century the position of the poor agricultural classes in England was singularly favorable. The price of wheat was both low and steady. Wages, if they advanced slowly, appear to have commanded an increased proportion of the necessaries of life, and there were all the signs of growing material well-being. It was noticed that wheat bread, and that made of the finest flour, which at the beginning of the period had been confined to the upper and middle classes, had become before the close of it over the greater part of England the universal food, and that the consumption of cheese and butter in proportion to the population in many districts almost trebled. Beef and mutton were eaten almost daily in the villages.

Johnson wrote:

There every bush with nature's music rings
There every breeze bears health upon its wings.

However, there were even at this time some who saw beneath the surface of abundance and prodigality. An economist, Rogers, pointed out that the prosperity was all on the side of the ruling classes and the capitalists, while the laborers were in "irremediable poverty and without hope." Their wages were artificially fixed by the quarter sessions and they were kept "in a condition wherein existence could just be maintained."

Creighton writes:

> But the Eighteenth Century, even the most prosperous part of it, from the accession of George I to the beginning of the Industrial Revolution in the last quarter or third of it, was none the less a most unwholesome period in the history of England. The health of London was never worse than in those years, and the vital statistics of some other towns, such as Norwich, are little more satisfactory.

In 1782, White wrote of the fever in London:

> The annual deaths under the old regime exceeded by a good deal the annual births; in the seven years, 1728-35, according to the figures in the parish registers, the burials from all causes were 3,488 and the baptisms 2,803, an annual excess of 98 deaths over the births in an estimated population of 10,800 (birth rate 37 per 1,000, death rate 46 per 1,000).

Creighton says:

> The mean annual deaths were never higher in London, not even in plague times over a series of years, the fever deaths keeping pace with the mortality from all causes, and, in the great epidemic of typhus in 1741, making about a fourth part of the whole. The populace lived in a bad atmosphere, physical and moral.

It is stated that the consumption of alcohol in London amounted to six gallons per head per annum. A duty of 20 shillings per gallon did not prevent the poor from getting it, and large quantities of gin were smuggled in from Holland. In 1726 the College of Physicians presented this matter to the House of Commons with the following statement:

> We have with concern observed for some years past the fatal effects of the frequent use of several sorts of distilled spirituous liquor upon great numbers of both sexes, rendering them disease, not fit for business, poor, a burthen to themselves and neighbors, and too often the cause of weak, feeble and distempered children, who must be, instead of an advantage and strength, a charge to their country.

The poor in London were crowded into small quarters. In 1737 one house was found to contain eleven married couples and fifteen single persons. A tax was levied on each window in the house and each window in the cellar, stairway and outhouse was counted and skylight included. "No window or light shall be deemed to be stopped up unless such window or light shall be stopped up effectually with stone or brick or plaster on lath."

Debtors were thrown into prison where some remained for years and if they had any comforts in the prison they had to pay for them. Jailers grew rich out of the necessities of their wards. Those unable to pay were crowded into unbelievably small quarters. The first commission to inquire into these abuses reported:

> George's ward, sixteen feet by fourteen and about eight feet high, had never less than thirty-two in it all last year and sometimes forty; there was no room for all to lie down, one-half the number sleeping over the others in hammocks; they were locked in from 9 p. m. to 5 a. m. in summer, longer in winter, and as they were forced to ease nature within the room, the stench was noisome beyond expression.

It is a matter of common knowledge that the work of prison reform in England at the time of which we write was due largely to the efforts of John Howard and his work was begun in 1773.

While the great landowners accumulated wealth, the poacher who snared a rabbit was sent to jail or deported. The condition of the poor was hopeless and the best blood of England flowed willingly or unwillingly into the United States, Canada and Australia. However, typhus often pursued the poor emigrant in his flight by sea and it is said that one-third the immigrants to America in the eighteenth century died during or soon after the voyage. It is well known that the fatality from ship fever continued through the early part of the nineteenth century. During the American War (1774-1780) the number of British seamen raised was 175,990, the number of those who died of disease was 18,545, and the number killed was 1,243.

It is interesting to note that during the eighteenth century English physicians for the most part were not much concerned with the poor and many of them saw but little typhus, while a colleague busy among the poor saw much of it. A Dr. Moss, writing of diseases in Liverpool, said that typhus was rare at a time when Dr. Currie was seeing more than 3,000 cases a year. In 1790 Liverpool was the second city in England, with a population of 56,000, while that of London was estimated at 800,000. According to Currie 7,000 of the people of Liverpool lived in cellars and 9,000 more in back houses with small courts and with narrow passages to the streets. In ten years (1787-1796) 31,243 cases of fever were registered, an average of 3,124 per year. In the last quarter of the eighteenth century Chester was regarded as the most desirable residence city in the kingdom. Within the walls, it had a population of about 3,500 and from 1764-1773 the death rate was only 17.2 per 1,000, but the poor lived outside the walls and Haygarth describes the condition as follows:

> The houses were small, close, crowded and dirty, ill supplied with water, undrained, and built on ground that received the sewage from within the walls. The people were ill fed and they seldom changed or washed their clothes; when they went abroad they were noisome and offensive to the smell. . . . In these poor habitations when one person was seized with the fever, others of the same family are generally affected with the same fever in a greater or lesser degree.

The second half of the eighteenth century saw the great manufacturing development of England by the employment of machinery. Now the poor were exploited by the manufacturer. The houses occupied by the operatives are said by Ferrier to have been dirty, without ventilation, and with the beds almost touching. "As soon as one poor creature dies or is driven out of his cell, he is replaced by another, generally from the country, who soon feels in his turn the consequences of breathing infected air." The only voices heard in behalf of the poor were those of medical men, and in Manchester Ferrier pleaded for them in strong language:

> I have seen patients in agonies of despair on finding themselves overwhelmed with filth and abandoned by everyone who could do them any service. . . . The situation of the poor at present is extremely dangerous, and often destructive to the middle and higher ranks of society. . . . The poor are indeed the first sufferers, but the mischief does not always rest with them. By secret avenues it reaches the most opulent and severely revenges their neglect or insensibility to the wretchedness surrounding them.

It was the fact that typhus occasionally found its way into the midst of the rich, and, when it did, killed so many and so quickly, that they were compelled to recognize that the misfortunes of the poor were of concern to themselves. Finally in a half-hearted way, urged by physicians, growling about the wastefulness and improvidence of the laboring classes, driven by the occasional deadly outbreaks in their own ranks, the ruling classes began to provide special hospitals for the isolation and care of cases of typhus. The London fever hospital was established in 1802.

The epidemiologic history of Britain during the Napoleonic wars presents many points of interest. Food prices were high. For a time American markets were closed to British manufacturers. Still, the period (1803-1816) was comparatively free from typhus, so far as Britain was concerned. In peace the poor man's business is to serve the rich, clothe himself in rags, rear his family in a stye and eat nothing. In war he becomes a hero, the defender of his king and country. He is well clothed, well fed and all that is asked of him is that he die for his country if need be. The wife and children at home must be cared for because more soldiers will be needed.

Immediately after the declaration of peace (1816) typhus began to increase and within another year it took on epidemic proportions. The condition of the London slums of the time is shown by a Parliament report as quoted by Creighton:

> Calmel's Buildings, a small court near Portman Square, consisting of twenty-four houses, in which lived seven hundred Irish in distress and profligacy, neglected by the parish and shunned by everyone from fear of contagion. George Yard, Whitechapel, consisting of forty houses in which lived two thousand persons in a similar state of wretchedness.

In 1831 typhus became epidemic in England and continued its ravages for more than ten years. The destitution and sickness among the poor of Manchester in the latter part of this epidemic (1839-1841) formed the basis of the story of "Mary Barton" written by Mrs. Gaskell. The author dwells on the bitterness on the part of the poor.

> The most deplorable and enduring evil that arose out of the period of commercial depression to which I refer, was this feeling of alienation between the different classes of society. It is so impossible to describe, or even faintly to picture, the state of distress which prevailed in the town at that time, that I will not attempt it; yet I think again that surely in a Christian land, it was not known so feebly as words could tell it, or the more fortunate and happy would have thronged with their sympathy and aid. In many instances the sufferers wept first and then cursed. Their vindictive feelings exhibited themselves in rabid politics. And when I hear, as I have heard, of the sufferings and privations of the poor, of provision shops where ha'porths of tea, sugar, butter and even flour were sold to accommodate the indigent—of parents sitting in their clothes by the fireside during the whole night for seven weeks together, in order that their only bed and bedding might be reserved for the use of their large family—of others sleeping upon the cold hearth stone for weeks in succession without adequate

means of providing themselves with food or fuel—and this in the depth of winter—of others being compelled to fast for days together, uncheered by any hope of better fortune, living, moreover, or rather starving in a crowded garret or damp cellar, and gradually sinking under the pressure of want and despair into a premature grave; and when this has been confirmed by the evidence of their careworn looks, their excited feelings, and their desolated homes—can I wonder that many of them, in such times of misery, and destitution, spoke and acted with ferocious precipitation?

In 1847-1848 there was a revival of typhus, under the name of "Irish Fever," in England. The last epidemic in England occurred in 1863-1864, and was in part due to the "cotton famine" resulting from the civil war in our own country. Since that time typhus has gradually decreased in Britain, but has not entirely disappeared.

From the fact that I have dwelt on typhus in Britain, it must not be inferred that it was unknown or was less prevalent on the continent of Europe during the seventeenth, eighteenth and nineteenth centuries. It was constantly present and assumed epidemic proportions of varying intensity in diverse places at different times. No European nation has been wholly free from it and it has continued to develop epidemics, especially in Austria and Russia. The present war has developed the conditions most favorable to its dissemination and I shall not attempt to predict the part it may play in the savage struggle now going on.

Taking Europe as a whole, the period from about 1670 to about 1850 may be considered as the typhus age. This does not mean that this disease did not exist before this period or that it ceased with the close of it. Neither assumption would be true, but before that time typhus was overshadowed for many centuries by the more deadly plague. Still it is a question if even at that time typhus did not kill more than the plague. The former was constantly present while the latter lapsed from time to time apparently on account of lack of susceptible material. Even during the typhus age other deadly infections, as smallpox, tuberculosis, diphtheria, etc., aided in rolling up heavy mortality lists. A complete history of typhus would be a valuable contribution to human knowledge and should be studied by statesmen and all interested in the welfare of the race, as well as physicians. There is certainly one great lesson which it teaches and that is that the health conditions of the poor are of interest to all. No nation can be great so long as its laboring classes live under unhygienic conditions. Typhus impoverished Europe not only by its high mortality but by the great emigration from its shores, leaving the degenerate to beget its generations.

Before leaving the history of typhus in Europe, I wish to quote the definition of the disease given by the greatest English authority of the nineteenth century, Murchison:

> A disease attacking persons of all ages generated by contagion, or by overcrowding of human beings, with deficient ventilation, and prevailing in epidemic form, in periods or under circumstances of famine and destitution. Its symptoms are: more or less sudden invasion marked by rigors or chilliness; frequent, compressible pulse; tongue furred and ultimately dry and brown; bowels, in most cases, constipated; skin warm and dry; a rubeoloid rash appearing between the fourth and seventh days, the spots never appearing in successive crops, at first slightly elevated, and disappearing on pressure, but, after the second day, persistent, and often becoming converted into true petechiae; great and early prostration; heavy flushed countenance; injected conjunctivae; watchfulness and obtuseness of the mental faculties, followed at the end of the first week by delirium, which is sometimes acute and noisy, but often low and wandering; tendency to stupor and coma, tremors, subsultus, and involuntary evacuations, with contracted pupils. Duration of the fever from ten to twenty-one days, usually fourteen. In the dead body no specific lesion; but hyperemia of all the internal organs, softening of the heart, hypostatic congestion of the lungs, atrophy of the brain, and oedema of the pia mater are common.

Typhus fever became epidemic in Mexico soon after the conquest (1530) and has continued in endemic form with occasional severe exacerbations to the present time. According to Liceaga the second recorded epidemic occurred in 1545 and the third in 1575. In 1736-1737 the disease is said to have killed 192,000. During the nineteenth century there were many exacerbations, the most extensive of which was in 1861. At the present time typhus is common in Mexico.

Importations of typhus by immigrants into this country have been constant and it is probable that at no time have our large cities been wholly free from it, but in most instances it has been limited to recently arrived immigrants and those directly in contact with them.

Doty says: "Out of 439 cases of typhus fever which occurred in New York during 1892-1893, 434 were removed from the poorer tenement and lodging houses, principally the latter."

In the records of the Civil War 1,723 cases with 572 deaths are reported under this name, but the diagnosis of many of these were questioned by the best medical officers, such as Woodward and Clymer. No cases were reported by Confederate officers. It is certain that typhus did not play any marked part in the mortality of that war.

THE TRANSMISSION OF TYPHUS

In 1909 Nicolle, stationed in Algiers, made two notable discoveries concerning the transmission of typhus fever. In the first place, he induced the disease in the chimpanzee by injecting the blood of patients and in like manner he transferred the disease from the chimpanzee to the macacus monkey. He was not able to transfer the disease in this way directly from man to monkey, but could do so indirectly through the chimpanzee. This suggests that the virus is increased in intensity by passage through the chimpanzee. In the second place, Nicolle succeeded in transmitting typhus from monkey to monkey by the bite of the body louse. Typical eruptions were secured in the chimpanzee constantly, but not uniformly in the monkey.

The fact that typhus is transferable by the bite of the body louse has been confirmed by Anderson and Goldberger, Ricketts and others. This renders it desirable for us to know as much as possible concerning the life history of this parasite. Shipley of Cambridge, England, has recently made studies along this line and I follow him principally in the following statements. The body louse (*Pediculis vestimenti*) is somewhat larger than the head louse and carries longer antennae. The male is about 3 mm. long and 1 mm. broad. The female is about one-tenth larger. Its color is said to vary with that of the people on whom it feeds, black, brown, and with different shades of grayish white. It does not move about over the surface but is always attached to the inner side of the underclothing. Even in feeding, it remains attached by at least one of its six legs to the clothing. When a lousy person is stripped, no lice can be found on him, but the inner side of the underclothing may be alive with them. When grown for the purpose of study, they must be permitted to attach themselves to bits of flannel and these must be brought into contact with the skin and the lice allowed to eat twice a day. They take hold promptly and feed greedily but never detach themselves from the flannel. The female after pairing begins to deposit eggs or nits at the rate of about 5 per day. These hatch after periods which vary markedly with the temperature. Cold delays hatching, but even freezing does not destroy the nits. Under favorable conditions the larvae emerge about the sixth day, and the larvae immediately begin to feed. Body lice seem not to be hardy and soon die unless they have frequent opportunity of feeding, but the clothing may carry nits quite indefinitely and these may hatch when the conditions become favorable. The newly hatched do not survive more than thirty-six hours without food. The lice are easily killed by gasoline or benzine or by turning the underclothing inside out and carefully applying a hot iron. Special attention should be given to the seams. Boiling quickly destroys both the insects and their eggs. It will be seen that as simple as these requirements are in ordinary life they are quite impracticable to the soldier in the trenches, especially when he has no change of underclothing. It is said that this parasite feeds only on dirty people and that it will not infest those who wear silk; but the soldier must be dirty, sometimes at least, and he is not supplied with silk underwear. Gasoline and benzine cannot be used by the soldier on account of their ready inflammability. A dilute solution of lysol or cresol soap made into a lather is applied to the inside of the clothing and left there to dry. Physicians and nurses in caring for typhus patients are exposed to great danger and the death rate among them has always been high. In recent years more than one medical man has contracted typhus in trying to solve its etiology and of the six American physicians who have recently studied typhus fever in Mexico three have contracted the disease and two have died—Conneff of the State University of Ohio and Ricketts of the University of Chicago. These are names now added to the martyr roll of science. Of Ricketts, his teacher and friend, Hektoen, has deservingly said:

> Those near him know that he fully understood the dangers to which he would be exposed and the risks he would run. He decided he would take those risks, meet the dangers with all possible means of prevention, and do the work that would come to his hands. And so he made the great sacrifice and gave all that a man can give to his fellow men.

Other American medical men and nurses have given their lives in the combat with this disease in desolated Serbia and others still are there and elsewhere in war-scourged Europe, seeking not to destroy but to save lives, fighting under the great battle flag of humanity and science.

Quite independently of the work of Nicolle, Anderson and Goldberger, Ricketts and Wilder, Conneff and others studied the etiology of typhus in Mexico. They found that the disease could be transmitted from man to the lower monkeys, without passage through a chimpanzee, that the virus in the blood is removed by filtration through porcelain, that one attack in the monkey gives immunity and that Nicolle was right in his claim that the disease is transmitted by the body louse. All attempts to transfer the disease by fleas and bed bugs have failed, while those with the head louse (*Pediculis capitis*) have not given uniform results.

For some years Brill has observed a peculiar disease in the wards of Mount Sinai Hospital, New York, and up to the present time he has records of about three hundred cases. Brill has described this disease as follows:

> An acute infectious disease of unknown origin and unknown pathology, characterized by an incubation period of from four to five days, a period of continuous fever, accompanied by intense headache, apathy, and prostration, a profuse and extensive erythematous maculo-papular eruption, all of about two weeks duration, whereupon the fever abruptly ceases either by crisis within a few hours or by rapid lysis within three days.

Anderson and Goldberger have shown that Brill's disease is typhus fever by injecting the blood of patients into monkeys and thereby establishing immunity to typhus.

Nicolle has reduced typhus in Tunis from 838 cases in 1909 to 22 cases in 1912. The only measure employed consists in freeing the people of lice.

THE ORGANISM

Plotz has isolated the organism and with Olitsky and Baeher has shown by complement fixation and agglutination tests that he has, most probably, found the infecting agent. In the agglutination tests only positive reactions in dilutions 1:50 were considered.

> Of twenty-four cases tested before the crisis all were negative except two which were tested one day before the crisis, both of which had a titre of 1:100. Of ten cases tested on the day of the crisis, three were positive and seven negative. After the crisis, thirty-eight cases were studied, 92.6 per cent. of which were positive. Agglutinins have been demonstrated as late as five months after the crisis. Of a very large series of control cases, no case gave a reaction in a dilution above 1:50, except three cases in which the occurrence of a previous attack of typhus fever could not be excluded. In these cases the reactions varied from 1:100 to 1:200. Control studies made by testing the serum of typhus cases against various other organisms were negative.

The opsonic index increases at the crisis and remains high in the convalescent stage.

> The organism is a small gram-positive bacillus, from 0.9 to 1.93 microns in length, the breadth being from one-fifth to three-fifths of the length. It is not acid-fast, has no capsule, and polar bodies can be demonstrated by appropriate methods. When first isolated, it grows only anaerobically, but after a time it can be grown aerobically.
>
> Intraperitoneal inoculation of a pure culture of the organism into guinea-pigs produces a rise of temperature in from twenty-four to forty-eight hours, the temperature remaining high for four or five days, and then dropping by crisis. This corresponds to the reaction seen in guinea-pigs after inoculation with defibrinated blood from typhus fever patients, except that the incubation period is shorter. Serum from a convalescing typhus patient has bactericidal properties against the organism obtained from Brill's disease and typhus fever.

Diseases with Highest Mortality.—According to the 1913 report of the Census Bureau, nine diseases cause more than half the deaths in the registration area comprising 65 per cent. of the population of the country. The diseases and number of deaths are as follows: tuberculosis, 93,421; heart diseases, 93,142; pneumonia, 83,778; nephritis, 65,106; diarrhea and enteritis, 57,080; cancer, 49,928; cerebral hemorrhage, 47,220; diphtheria, 11,920, and typhoid, 11,323.

HYPERTONIC SALT AND ALKALI SOLUTION IN SALVARSAN ANURIA *

R. T. WOODYATT, M.D.
CHICAGO

A man aged 45 had an aneurysm of the thoracic aorta extending from the diaphragm upward. The diagnosis was based on the character and distribution of the pain, the existence of cardiac hypertrophy with a peculiarly metallic aortic closure, a history of lues, a positive Wassermann reaction in the blood, and a roentgenogram. No other explanation of the symptoms was found in spite of an exhaustive study.

This patient had been treated with iodids and mercury, and had at first improved, but later suffered excessively from pain. He had then been given salvarsan. Within eight days he received three doses of 0.3, 0.3 and 0.4 grams respectively of old salvarsan. Forty-eight hours after the last one he felt ill and had a temperature of 99 F. During the day this rose and at 8 p. m. it was 102. He then complained of headache and slight nausea. The bowels had not moved. He grew very thirsty and drank water freely, but until noon of this day he had passed only 200 c.c. of urine. The urine was dark and contained a trace of albumin. After 1 o'clock he passed no urine at all. Examination revealed no palpable edema and no demonstrable ascites. He was taking in water and putting little out, still this water was not palpably accumulating in superficial regions. A tentative diagnosis was made of salvarsan poisoning.

Arsenic is one of that group of substances whose effects on the tissues and on the metabolism as a whole closely resemble that of tissue or general asphyxia. In respect to its effects on the structure of the tissues and on their metabolism, it belongs in the same general category with phosphorus, chloroform, hydrazin, and a long list of narcotic drugs. These all produce, in different degrees and admixtures, cyanosis with increased blood and tissue acidity, cloudy swelling and fatty infiltration of the cells of the viscera, especially of the liver and of the kidneys, but to a less degree of all cells. This parenchymatous degeneration goes on in the case of some of these drugs to the point of necrosis. A tendency to multiple hemorrhage is common. The nature of the changes in salvarsan poisoning has been studied extensively and is too familiar to require description here. Swelling, due to the imbibition of water by the parts most affected, would in the present case have accounted for the obvious water retention without tangible subcutaneous edema, and it was thought probable that the liver was swelling, the kidneys swelling, and perhaps also the brain and other viscera. As a matter of fact, the edge of the liver was easily palpable, soft and somewhat tender. The urine had contained albumin prior to its stoppage, and, as stated, the patient complained of headache and a little later became mildly delirious, all of which symptoms and signs were in keeping with the presumption of a liver, kidney and brain swelling or edema.

The relationship between asphyxia of a tissue and the rate at which acids accumulate in such a tissue is well established. The survival formation of lactic acid in a muscle which is immersed in an atmosphere of hydrogen and its rapid disappearance in an atmosphere of oxygen has been measured and timed with faultless precision by Fletcher and Hopkins. The great increase in the rapidity of lactic acid formation in surviving muscles when chloroform vapor is allowed to surround them has also been shown by the same writers, and the increased output of lactic acid in the urine, together with an actually increased hydrogen ion acidity in the blood, has been repeatedly demonstrated in asphyxias of various sorts and specifically following intoxications with narcotic drugs, phosphorus, arsenic and other members of that group whose characteristic tendency is to check cell respiration.

The power of acids when added to protein colloids so to alter these substances that they swell with the imbibition of water has been emphasized by the work of M. H. Fischer, and the power of acids when introduced into the tissues of the body to cause swelling, water retention, cloudiness of the cells, in short, edema, has been regarded by him as a phenomenon of the same nature as the swelling of protein gels in the test tube. That drugs of the group named do produce both acid, secondary to asphyxia, and edema of the parts where the action is most intense, is common knowledge.

Fischer's proposal to meet such conditions by bringing alkali into the tissues to neutralize any excess of acid which may still be there in neutralizable form, and simultaneously to bring into them sufficient quantities of a suitable neutral salt to dehydrate the neutral but still swollen tissue colloids, has been tested in this laboratory by E. A. Graham in experimentally produced chloroform intoxication in animals. Graham determined the doses of chloroform which, when given to animals of certain weights, always produced the severe symptoms of late chloroform poisoning, including the characteristic central lobular necrosis in the liver, along with edema, fatty infiltration, etc. When in animals of the same weight the same dose of chloroform was given and then followed by a suitable intravenous dose of hypertonic sodium chlorid with sodium carbonate in the form known as Fischer's solution, the necrosis was modified or failed entirely to appear.

Since chloroform and arsenic (hence salvarsan) are, as stated, closely related in their effects on the tissues and on the metabolism, the case mentioned above seemed an appropriate one in which to try the benefits of a salt alkali therapy.

Accordingly the patient was given 200 c.c. of Fischer's solution by bowel and two hours later the dose was repeated. This was at 9 p. m. The second dose was given at 11 p. m. It was also ordered that the patient take no food or any drink except lemonade to which sodium bicarbonate had been added until there was no longer any effervescence. The purpose of this was to provide that no fluid should be taken into the body without containing a suitable concentration of salt (in this case chiefly citrate) to carry it through, or, in other words, to make it diuretic for a normal individual, thus lessening the chance of vitiating the effect of the supertonic solution by bowel with a large quantity of subtonic solution by mouth, to do which, of course, would be equivalent to making up a supertonic solution and then promptly destroying its supertonicity by dilution before it was given. The bicarbonate was added merely for consistency to make the fluid taken by mouth alkaline rather than acid. As a matter of fact, the increasing nausea culminated in vomiting at about 10 o'clock, after which the patient slept for a

---

* From the Otho S. A. Sprague Memorial Institute Laboratory of Clinical Research, Rush Medical College.

time, so that little of the lemonade was taken. At about 10:30 the nurse reported the appearance of a florid erythematous rash over the face, neck and trunk.

At about 3 a. m., or four hours after the second salt alkali enema, there was a watery stool, and the patient passed 45 c.c. of urine. Between 6 and 7 a. m. he passed 120 c.c. more. A third injection of 200 c.c. of Fischer's solution was given by bowel and retained. By noon the urine totaled 600 c.c. The delirium and headache cleared and the nausea disappeared. The temperature fell to 99.

For the next two days the patient was given fruit, fruit juices and soft cooked vegetables with rusk, butter and cream. He was allowed water *ad libitum*, with potassium citrate, 20 grains, four times a day, and sodium bicarbonate, 60 grains, three times a day. On the second day the urine totaled 990 c.c., and at the end of the week averaged 1,500 c.c., although during the week there were minor diminutions of urine and periods of malaise and headache. Ultimately there was complete recovery, and since this experience the patient has received three doses of 0.4 gram of old salvarsan by vein at three-week intervals with no apparent injury and with considerable ameliorations of the general conditions.

In view of the fact that this patient was constipated when treatment was begun, that he received 1 gram of old salvarsan within a week, that symptoms first appeared after a characteristic delay and then included fever, albuminuria and urinary suppression, nausea, vomiting, headache, delirium and an erythematous rash, this case is recorded as one of a salvarsan reaction sufficiently serious to occasion grave concern, in which a sharp turn for the better followed by ultimate recovery took place within a few hours after the administration by bowel of an alkaline hypertonic solution (Fischer's solution) with no other therapy. An isolated experience of this sort is considered as suggestive that a suitable application of the same general therapeutic principles might prove of value in intoxications of the type described.

104 South Michigan Avenue.

THE EFFECT OF ALTITUDE ON BLOOD PRESSURE

WITH MINOR MISCELLANEOUS OBSERVATIONS

F. C. SMITH, M.D.
Passed Assistant Surgeon, U. S. Public Health Service
WASHINGTON, D. C.

Just what normal blood pressures are, at sea level and elsewhere, is a matter concerning which there is the widest diversity of opinion. Goodman[1] states that the systolic readings for normal young adults are from 120 to 130, and the diastolic about 85. Making the usual allowance for posture, digestive action, psychic disturbances, etc., he thinks that a systolic pressure of more than 140 is pathologic. Harlow Brooks[2] mentions 120 as the usual systolic pressure, but finds that in persons whose occupations entail mental activities it normally ranges between 140 and 155. Janeway[3] states that "in the great majority of young males 100 to 130 mm. will be found," and names the normal diastolic pressure as from 65 to 110. Faught[4] states that 120 may be taken as the normal systolic pressure in the male at age 20, and adds 1 mm. for every additional two years of life. He believes that the question as to what variations from this are normal cannot be definitely answered, but suggests 17 mm. above or below, or a total variation of 34. Barach and Marks[5] conclude that in 90 per cent. of healthy young men the systolic pressure is below 150, and in 96 per cent. the diastolic is less than 100. These readings are presumed to have been made at or near sea level. Among others who have made careful study of the normal blood pressure, but with special reference to the effect of altitude, are Gardiner and Hoagland,[6] Schneider and Hedblom,[7] and Pomeroy.[8]

To the study of blood pressure in health I have to contribute only the readings made at Fort Stanton (altitude 6,230 feet) on fifty-four young adults, of whom seventeen were females. In this series, as in the others here reported, the auscultatory method was used and diastolic pressures read at the fifth phase or point where pulse sounds disappeared.

TABLE 1.—BLOOD PRESSURE IN THE HEALTHY

* As pointed out by Norris (Blood Pressure: Its Clinical Application), blood pressure as ordinarily referred to is the difference between atmospheric pressure and the *absolute blood* pressure and is purely relative. The absolute pressure, both *atmospheric* and arterial, is of course constantly lowered by increasing altitude.

Our average systolic reading in the healthy was 129 for men and 121 for women; the average diastolic reading was 84 and 82 for men and women, respectively. It must be said, however, that averages are not very helpful in arriving at conclusions on this subject. We are inclined to believe that the effect of altitude on normal blood pressure has been frequently overestimated and sometimes confused with that of other influences.

Opportunity to observe the effect of altitude on blood pressure in the tuberculous has been afforded by the fact that about 150 patients are transferred each year from the coast to this station. For more than a year manometer readings have been made at all the hospitals belonging to the Public Health Service immediately before transferring a patient. Uniform methods of observation were prescribed by the Surgeon-General in general order, and the minimum width of the cuff fixed at 10 cm. The technic at this station has been uniform and carefully followed. The two aneroid instruments in use, the Faught and the Tycos, respectively, were checked up with a mercurial instrument from time to time and with each other, and have been found constantly correct. The personal equations of the various officers engaged in taking readings have been compared. Only one systolic reading was made at the marine hospitals located at sea level. This is compared with the systolic pressures made on the four successive days after arrival at this station. Pressures are considered the same when one reading at this station has been found to coincide with one at sea level, and when one or more higher readings coincident with one or more lower were found. Obviously, the comparison cannot be exact. At present, systolic and diastolic readings are being made at the principal stations located at sea level for four days before transfer, and it is expected that a more exact comparison can be offered next year.

The psychic disturbance occasioned by a three or four day transcontinental journey ending in a stage ride of 8 miles is considerable. Patients arrive excited by the knowledge that here the last stand in the fight against their disease is taken. It is not surprising, therefore, to find that in some cases the blood pressure was found higher here than at lower altitudes, and this regardless of any effect altitude may have. Out of 169 cases, systolic pressures were practically the same in 118, slightly higher in 23, slightly lower in 8, considerably higher in 15, and considerably lower in 5.

The effect of altitude on blood pressure in the tuberculous does not appear to be great, and when due allowance is made for disturbing factors, there is nothing found in our observations to indicate that an altitude of 6,230 feet has any pronounced influence on this phenomenon in the ordinary case.

MISCELLANEOUS OBSERVATIONS

The effect of tuberculosis itself on blood pressure is too well known to require comment. Authorities seem to be in complete accord that hypotension always prevails in uncomplicated active disease. The classes of tuberculous patients included in Table 3 have been the subject of discussion in recent literature on blood pressure, and the observations are believed to be of some value. The number in each, forty-three, was so fixed because that was the number of patients having frank hemorrhage during the period of observation. It may be noted here that it is not practicable to study the effect of prolonged residence on blood pressure in the tuberculous. Such an attempt would resolve itself into a study of the results of treatment and the effect of improvement or loss on blood pressure.

A AND B HEMOPTYSIS

More than casual interest has been taken in hemoptysis at this station, owing to the large number of fatalities (10 per cent. of all deaths) occurring here from pulmonary hemorrhage. A report of fifty-six such deaths appeared in the *Public Health Reports*, No. 51, in 1910. In the present study of the correlation of blood pressure and hemoptysis, the systolic readings of those having pulmonary hemorrhage are compared with those of carefully matched cases free from hemorrhage. Both early and late cases are included in the series. In matching a hemorrhage case with a nonhemorrhage case, careful attention to details was given, and they are as nearly alike as possible in age, race, extent and duration of disease, in prognosis where the patients are still under treatment and in result where treatment has terminated. Patients with manifest complications were excluded from both classes. The readings are the average of those taken at the regular bimonthly examinations and are therefore not modified by the influence of hemorrhage. Nothing was found to support the contention of those who believe that most hemoptyses occur in those with high systolic pressure.

C, D AND E RESULTS

The systolic pressures of forty-three patients who died are compared with those of an equal number of patients with far advanced disease who made an apparent cure or an arrestment, and also with those of patients suffering from the effects of altitude. These men had been under treatment for about a year, although not all at the same time, and many readings were made on each, of which the average was taken for use in Table 3. Column C, on favorable results, contains the record of our best results of treatment, all patients referred to therein having confirmed an arrestment of disease by at least two months of continuous employment. Comparison with the readings of other observers shows no great variation from manometer readings in similar cases at sea level. There is apparent neither depression due to altitude, except possibly in Column E, where readings were made on those suffering from dyspnea, nor the elevation of blood pressure claimed by one or two observers to occur at 6,000 feet, and which they presumed to indicate the advantages of altitude in treating tuberculosis. It seems extremely doubtful whether moderate altitude has any pronounced effect on blood pressure in the tuberculous, except possibly in those whose circulatory apparatus is unable to accommodate itself to the increased strain thus put on it by adverse influence. Sufficient data are not yet available to determine which is cause and which effect in this phenomenon.

INDUCED PNEUMOTHORAX

The influence of induced pneumothorax on blood pressure has been studied on sixteen patients who have been treated by this method for about seven months. The effect of the excitement of operation itself was excluded by taking the manometer readings at another time. The readiness with which fallacious results in blood pressure may be obtained was exemplified when the readings of one set of observers were found to show a marked increase of blood pressure in all patients in this group. But when the readings of all the observers were averaged, it was found that this was due to that large variation in blood pressure found in some individuals without apparent cause. Taking all the readings, which extended for several months and in some instances more than a year before treatment by induced pneumothorax was instituted, it is found that there have been no important changes in the blood pressure of the individuals treated. In one there appears to have been a temporary increase and in another a temporary decrease during the first month of compression, both returning to the original readings after a few months. In two individuals there was a slight increase in blood pressure, which began soon after treatment was instituted and which has continued to the present time. This reached in one instance from 2 to 14 mm. Hg systolic pressure, and in the other from 6 to 18 mm. Hg.

The blood pressure in both right and left arms was observed in induced pneumothorax patients to determine the effect of the treatment. No greater difference in the two arms was found than is normal except in one case of incomplete compression, pleural adhesions being present, in which the readings in the right arm were 114 systolic, 98 diastolic, and in the left arm 132 systolic, 88 diastolic. This patient's right lung was the one compressed, and it seems not improbable that the nitrogen contained in the pleural cavity had some direct influence on the circulation on that side. Four months later, after reexpansion of the lung was nearly completed, the manometer readings on the right arm were systolic 120, diastolic 94; left arm, systolic 128, diastolic 86. No great importance is attached to the aberrant readings in this case, and it is our impression that in uncomplicated cases of induced pneumothorax, when compression is effected with the usual caution, no pronounced effect on blood pressure results.

ACKNOWLEDGMENTS

The blood pressure readings at sea level were made by the various officers of the Public Health Service stationed at marine hospitals belonging to this service. All the junior officers on duty at this sanatorium have assisted in the routine blood pressure measurements made here. Acting Assistant Surgeons William Keiller and F. S. Littlejohn made the special readings on the healthy and on those treated by induced pneumothorax, respectively.

INFECTIONS WITH HEMOGLOBINOPHILIC BACTERIA *

DAVID JOHN DAVIS, M.D.
CHICAGO

The hemoglobinophilic bacteria comprise a rather large group of bacilli which grow only in an artificial medium containing hemoglobin. This group does not include the many bacteria that, while growing better in mediums containing blood or blood serum, will also grow in mediums not containing hemoglobin. Its representative organism and by far its most important member is Pfeiffer's bacillus (*B. influenzae*), which was discovered by Pfeiffer in the respiratory tract of patients afflicted with influenza during the great pandemic, in 1889-1890. Not only did he discover and isolate this organism at that time, but he definitely proved its hemoglobinophilic character, a property of bacteria hitherto unknown. In his classical paper[1] in which he reported these researches he also described other organisms differing in certain respects from the true influenza bacilli but similar in being hemoglobinophilic. These he called pseudo-influenza bacilli. Since then these pseudo forms, which have also come to be commonly referred to as influenza-like bacilli, have been found especially in the upper respiratory tract in a variety of diseases.

[1] Pfeiffer: Ztschr. f. Hyg., 1893, xiii, 357.

I have gone over my data which have accumulated on this subject during the last several years and have arranged it in tabular form (see table). The isolation of the bacilli was made on blood-agar plates, usually using human or rabbit's blood. Except the tonsils, the material examined was either the sputum or swabs of the pharynx.

Especial attention was given to the detection of this particular group of organisms in all the examinations. They were not made in the various clinical conditions because there was any reason to think an infection with hemophilic bacteria existed. Therefore they are not selected cases in any sense. The data, furthermore, was collected during a period of several years, no essential difference being noted from year to year; the presence of hemophilic bacilli therefore cannot be explained by assuming the existence of a possible seasonal epidemic of influenza.

It will be seen from the table that hemophilic bacilli are very common in different kinds of infectious diseases. Probably in all except the influenza meningitis cases, there is no good reason to look on them as primary infections, but simply as secondary invaders, which find a suitable environment in connection with lesions produced by other and usually more virulent organisms.

TABLE SHOWING OCCURRENCE OF HEMOPHILIC BACTERIA IN VARIOUS INFECTIOUS DISEASES

Disease	No. Cases	Hemophilic Bacilli Present	Per Cent. Positive
Influenza (grip)	40	7	17
Bronchopneumonia	26	10	38
Lobar pneumonia	12	4	33
Measles	23	13	56
Varicella	11	7	64
Pertussis	68	61	89
Pulmonary tuberculosis	5	3	60
Acute articular rheumatism	11	0	0
Epidemic meningitis	11	4	30
Influenza meningitis	7	7	100
Tonsil crypts	300	3	1
Normal throats	20	2	10
Total	534	121	23

In the forty cases of clinical influenza or grip, 17 per cent. of the examinations yielded hemophils. They comprise cases from epidemics occurring in two different years, each of which gave approximately the same results. Streptococci, pneumococci and *Micrococcus catarrhalis* were the principal organisms found, sometimes one, sometimes another, predominating; often the types were about equally mixed.

In pertussis they are present in nearly every case, some time during the course of the disease, usually after the paroxysmal stage sets in. They may remain in the throat for a considerable period of time after the symptoms disappear. In some cases the bacilli are very numerous and on the plates are in almost pure culture, while in other cases they are few. They may be persistently absent and then suddenly appear in enormous numbers and thus continue. Pneumococci and streptococci are nearly always found and not infrequently bacilli, *M. catarrhalis* and diphtheria-like organisms appear in the cultures in small numbers.

In measles they are common, especially in cases in which cough is a pronounced feature. *M. catarrhalis* was commonly found also. Varicella gave much the same bacteriologic findings as measles.

In lobar pneumonia, of course, the pneumococcus is as a rule the predominating organism in the sputum, while streptococci are usually present in small numbers. Influenza bacilli were present in the sputum four times in twelve cases examined. In one case it was interesting to note that even early in the disease (fourth day) these bacilli were present in typical pneumonic rusty sputum in numbers exceeding the pneumococci. In another case of a somewhat atypical pneumonia in which, however, pneumococci were obtained in the blood in pure growth, examination of the washed sputum on the fourth day of the disease gave 80 per cent. *M. catarrhalis* colonies and 20 per cent. pneumococcus colonies. No hemophilic bacilli were present. Subsequent examinations gave the same findings. Again, an elderly man became ill with symptoms of lobar pneumonia. The sputum at first was bloody and later became profuse and purulent. The clinical diagnosis of abscess of the lung was made. Examination of the washed sputum gave enormous numbers of hemophil colonies, chiefly in clusters around colonies of other bacteria. No pneumococci appeared in the plates. A few days later, death occurred. Postmortem examination showed lobar pneumonia with several abscesses in the lungs. Pus from an abscess gave pneumococci 60 per cent., streptococci 35 per cent., *Staphylococcus aureus* 5 per cent.; no hemophils. These cases are instructive as showing the variation in the bacterial flora not only in complicated cases, such as the last, but even in typical cases of pneumonia.

Only five cases of pulmonary tuberculosis were examined. Hemophils were found in the sputum in three of these. It has been observed by many that they are common secondary invaders in this disease.

In the epidemic meningitis cases they were found in the nose and throat four times in eleven cases.

In normal throats they are occasionally found. Swabs of the throat from twenty normal persons gave growth of influenza-like bacilli twice; they were present in small numbers.

In the tonsil examinations, all cultures were made on blood mediums from the depths of the crypts after the organ had been carefully incised and laid open. In all cases the tonsils were diseased to some degree and came from persons suffering from a variety of conditions. Forty-two were from patients with chronic joint disorders, ten from those with chronic nephritis, and forty from persons with endocarditis. Most of the remainder were removed because they were excessively hypertrophied, and came largely from children. Of the three hundred pairs of tonsils examined, in only three were influenza-like bacilli found, and then in small numbers and mixed with other bacteria. They were all from the group of cases of hypertrophied tonsils without other serious lesions. It is evident that by comparison with other conditions mentioned in the table, the hemophilic bacilli are rare inhabitants of the tonsillar crypts.

The total number of examinations made for the bacilli was 534, in 121 (23 per cent.) of which they were found. Excluding the tonsils, the total number examined was 234, in 118 (51 per cent.) of which they were present. The table shows they occurred fairly uniformly in the various diseases. It may be stated as generally true that they are found more frequently and in larger number in those cases in which there is involvement of the bronchi, especially the chronic cases with profuse expectoration, than in conditions like tonsillitis and acute rheumatism, in which the lesions are usually limited to the upper respiratory tract.

These bacilli are all very similar, indeed practically identical, and they also agree in all essential details with the description of Pfeiffer's bacillus as given by himself and by others. They differ from each other perhaps only in the matter of virulence, in which respect they seem to vary somewhat. As an illustration, I may refer to the organisms of this type already mentioned which not uncommonly cause acute meningitis in children. I have had an opportunity to study seven such cases,[2] all fatal, five of which were examined postmortem. They all occurred here in Chicago within the course of less than two years, at a time when an influenza epidemic did not exist. The onset in four was preceded by a "cold." The general course was that of an acute meningitis and did not differ essentially from the course of meningitis caused by pyogenic cocci. The hemophilic bacilli were found in immense numbers and in pure cultures in the spinal fluid and in the meninges and seemed to be identical with the true influenza bacillus, having, however, as a rule, a higher degree of virulence for animals. In rabbits after inoculation of relatively small doses they produce death by true septicemia, a result usually not possible to obtain with similar doses of Pfeiffer's bacillus.

In guinea pigs neither the hemophilic bacilli isolated from the respiratory tract of patients with the diseases noted in the table, nor those from the patients with meningitis are highly virulent. On the whole, the latter are slightly more virulent than the former, growth from two small agar-slants being sufficient, ordinarily, to kill in twenty-four hours after intraperitoneal injection. I inoculated the bacilli of this group into the human throat a number of years ago. The bacilli were isolated from the sputum of patients with whooping cough and swabbed into the tonsils and walls of the pharynx of a healthy young man who volunteered for this service. The inoculation was followed after forty-eight hours by definite symptoms of fever, redness of the throat with an abundant mucoid secretion and some cough. The symptoms lasted several days. In the abundant thick, tenacious mucus from the throat, influenza bacilli occurred in immense numbers and continued in the throat for at least four weeks. None was present in the throat before inoculation, as was shown by careful examination. I have also shown that bacilli of this type (hemophilic bacilli isolated from a case of bronchopneumonia) when injected in living cultures subcutaneously in the human, produced local swelling, redness and tenderness, and after several days an abscess containing yellow pus, in which the bacilli thrived and from which they were recovered in pure culture. These bacilli are therefore clearly pyogenic in character.

There can be no doubt, therefore, but that these bacilli may be to some degree pathogenic, and that while, like many other germs, they may be present without causing lesions, they are capable of producing reactions in the tissues and surely are not always harmless saprophytes in the human body.

This leads me to discuss further the relation of Pfeiffer's bacillus to epidemics of clinical influenza. In the literature there are numerous references to the occurrence of hemophilic bacilli in many infectious diseases and diseases of the respiratory tract. They have usually been referred to as influenza bacilli (Pfeiffer's bacillus), occasionally as pseudo-influenza organisms, and for the most part have been looked on as secondary invaders, except in influenza, in which the hemophilic bacilli have pretty generally come to be considered as the specific organism. Pfeiffer, in 1893, first announced this and since then an enormous mass of literature has accumulated, especially in Germany, much of which tends to substantiate the idea that his bacillus is the specific cause of this disease. If the evidence is carefully examined, however, it is found that in reality the specificity of this organism does not rest on any too sure foundation. It does not meet Koch's requirements. In many epidemics of influenza it is true they are found in the throat, being often present in large numbers, and they have been obtained from abscesses and numerous other lesions in the body. In postmortems the organisms have been found in large numbers, especially in the respiratory passages and the lungs. The pathogenicity of the bacillus for animals is low and the experiments of Pfeiffer with regard to the presence of toxins are not at all convincing. These facts are hardly sufficient to demonstrate beyond question that the organism is specific and that it is not merely a secondary invader.

It is interesting that the French, especially, have always been doubtful about the etiologic rôle of Pfeiffer's bacillus in influenza and they have presented many data in opposition to the view that it is specific for this disease. Elmassian,[3] in 1899, could not distinguish between organisms obtained from whooping cough, acute bronchitis, pulmonary tuberculosis and pneumonia. He considered them all identical with Pfeiffer's bacillus of influenza and said that it was not proved that this bacillus was the specific cause of grip. Sacquepee[4] studied a typical and very severe epidemic of grip in a garrison and found Pfeiffer's bacillus in only the latter part of the epidemic. At other times he found a gram-negative, motile, typhoid-like bacillus and also pneumococci and streptococci. He thinks that the influenza bacillus is not specific and that grip may not be due to any specific microbe. Bezançon and Israels de Jong[5] in an epidemic of grip studied the expectorations of twenty-five patients bacteriologically and found Pfeiffer's bacillus very rare. They called special attention to the *M. catarrhalis*, which was very common. They found pneumococci, streptococci, pseudodiphtheria bacilli, pneumobacilli and rarely staphylococci. They conclude that grip is not caused by Pfeiffer's bacillus, but is due to a variety of organisms of exalted virulence. Kleinenberger,[6] in twenty-seven cases of influenza, found them present in only eight cases. The *M. catarrhalis* was present in nearly every case. Von Jaksch[7] has described a condition under the name of pseudo-influenza which is indistinguishable clinically from influenza, but which is not caused by the influenza bacillus. He concluded that it was due often to a streptococcus invasion, because of the large number of these organisms found. In some the cause could not be determined, but he was sure it was not due to influenza infection.

Investigation of the literature on this point, therefore, corresponds very well with the findings as given in the table. While it is undoubtedly true that in many epidemics of influenza Pfeiffer's bacillus is commonly found in nasal and oral excretions, it is equally true that epidemics and also sporadic cases occur in which the condition appears to be identical with influenza clinically, but in which Pfeiffer's bacillus only occasionally appears, and other organisms such as pneumococci, streptococci and *M. catarrhalis* occur very commonly and in large numbers. The most rational interpretation of these facts seems to be that there are a number of organisms which may give clinically the same picture and which may exist in the respiratory passages either in pure culture or occurring together. The fact that many cases indistinguishable clinically from influenza occur both in sporadic and epidemic form, not associated with the influenza bacillus, should be more widely known, for ever since the great epidemic of 1889-1890, almost every disease bearing any resemblance at all to influenza is assumed, without a bacteriologic examination, to be an influenza infection. Attention should be called also to the fact that smears of oral and nasal excretions are very unreliable in the diagnosis of this disease, and that to be sure of an influenza infection, cultures on blood-agar plates should be made.

A further point of interest in connection with these bacilli is the fact that when grown on mediums in the presence of other bacteria, for example, streptococci, staphylococci, etc., they multiply more rapidly, their colonies are larger and their virulence for animals is increased. In other words, they clearly show to a marked degree the property of symbiosis.

Grassberger[8] called attention to the occurrence of very large influenza colonies in the immediate neighborhood of colonies of other bacteria, when grown with them on blood-agar plates. He worked especially with the staphylococcus, but the same effect is obtained with the influenza bacilli when grown with many other varieties. He observed influenza colonies as large as 4 mm. in diameter grown in this manner, which, in pure culture, are usually only 0.5 mm. or less. It is well known that influenza bacilli will live and develop through several generations on non-hemoglobin mediums, when grown in mixed cultures. Pfeiffer, before he discovered the use of hemoglobin for influenza culture, noted the growth of influenza bacilli on agar smears with sputum, but could not successfully transplant them on this medium in pure culture. M. Neisser obtained mixed cultures of *B. xerosis and B. influenzae* from conjunctivitis in measles and grew them through twenty generations on plain agar. Strains of hemophilic bacilli from throats of patients with measles, whooping cough and scarlet fever were in like manner carried through many generations in mixed culture. With dead *B. xerosis* or its extracts no growth occurred. He contends the presence of a living organism is necessary to produce this symbiotic effect.

Frequently in blood-agar plates inoculated from sputum or swabs, there is observed a conspicuous cluster of influenza-like colonies surrounding other colonies present on the plates, such as those of streptococcus, staphylococcus and pneumococcus. They are in this location not only larger but apparently more numerous than when farther away from foreign colonies. In order to obtain such an arrangement, it seems necessary to have a large number of influenza colonies in the plate and a few of the foreign organisms. When the former colonies are numerous, they are often so small that a hand lens is necessary to see them, but around the foreign colonies, as a result of some favorable influence, they become much larger and are more easily seen. This appearance may be easily obtained by sowing the blood-agar plate densely with the hemophilic bacillus and sparsely with some other organism, such as staphylococcus. In twenty-four hours the symbiotic relationship is usually evident.

The growth of several strains of these hemophilic bacilli was tested on various mediums and to each were added dead bacteria (staphylococci and streptococci) and filtrates of cultures. The results were uniformly negative. All the experiments performed indicated that symbiosis is dependent on the presence of the living organisms.

The symbiotic relation of other bacteria to influenza-like organisms is shown by the increased pathogenicity of the latter for animals. I have made a number of animal experiments to determine the effect of introducing another organism with the hemophilic bacilli, into the peritoneal cavity. This had been done with the influenza bacillus and the streptococcus by Jacobson, who found that the virulence of the bacilli could thus so be increased that much smaller doses of the bacilli alone would be sufficient to kill. He obtained both the bacilli and streptococci in the body fluids and heart's blood. In my experiments, non-virulent *Staphylococcus pyogenes aureus* was used; 2 c.c. of a broth culture of this organism produced no effect when inoculated into the peritoneal cavity of guinea-pigs. When 0.5 c.c. of this culture was inoculated with two blood-agar slants of the hemophilic organism, which, as above stated, rarely killed, death invariably followed in twenty-four hours or less. From the peritoneal exudate, both organisms were isolated. From the heart's blood, however, as a rule, only the hemophilic bacillus was obtained and no staphylococci. In two animals in which large amounts of staphylococci were injected, a few were obtained also in the heart's blood. After passing the bacilli in symbiosis with staphylococci through six animals, one blood-agar slant alone would kill an animal in twenty-four hours. Thus its virulence had been more than doubled. The effect of *M. catarrhalis* and an avirulent streptococcus on hemophilic bacilli was found to be very similar to that of staphylococcus.

The increased pathogenicity of this organism when growing with another organism is directly associated with the symbiotic phenomenon noted above and probably depends on the same factors. Under the conditions in which we find these bacilli in the throat, for instance, they are always associated with other organisms and therefore are thriving under circumstances which permit a manifestation of their greatest virulence and most luxuriant growth. It is also quite possible that the injurious products of such growth may be not only more abundant but even of a different and more toxic character and it would therefore be improper to draw conclusions from the data obtained by growing the organisms in pure culture.

Several other varieties of hemophilic bacilli, differing in certain respects and especially in relation to symbiosis have been described by a number of observers. Friedberger[9] found in the preputial secretions of dogs such an organism, a very minute, gram-negative bacillus which was not pathogenic for animals and did not show the phenomenon of symbiosis. Some years ago I described[10] a somewhat similar bacillus, isolated from pathologic urine from three patients suffering with cystitis, in which there was evidence that a causal relationship to the infectious process existed. This organism was non-symbiotic and non-pathogenic for animals. Since then, C. Koch[11] has described an identical bacillus which he believed to be the causal organism, in a number of cases of puerperal infections.

---

[8] Grassberger: Ztschr. f. Hyg., 1897, xxv, 453.

[9] Friedberger: Centralbl. f. Bakteriol., 1903, i; orig., xxxiii, 401.

Recently I obtained a somewhat similar bacillus from a large abscess of the shoulder joint in an infant a few months old. The child had been in the hospital for many weeks and was supposed to be a blue baby. He had clubbed fingers and became cyanotic when crying. Clinically there was evidence of a congenital heart lesion. Roentgenograms showed the heart dilated to the left, with evidence of a hypertrophied left auricle. Not only cultures of pus obtained from the abscess by aspiration, but also cultures of blood from the median basilic vein gave a pure growth of a minute, gram-negative, non-motile bacillus, which was strictly hemoglobinophilic and which resembled closely the influenza bacillus except in its symbiotic property. The same bacillus was grown from the bronchial secretion, and it was probably from this source that the organism entered the circulation and later localized in the shoulder joint. It grew readily on blood-agar under aerobic conditions. The colonies were about 1 mm. or slightly less in diameter, gray in color, slightly raised, moist and spreading, and were not hemolytic on blood-agar plate cultures. The organism showed a tendency to grow in clumps. In morphology, the bacillus was approximately the size of the influenza bacillus; bipolar staining was often observed. Short thread forms were commonly seen, simulating those in cultures of *B. influenzae*. The red blood count was 7,040,000; hemoglobin 100 per cent.; white count 18,300, which, when differentiated, gave small mononuclears 51, large mononuclears 7, polynuclears 40, eosinophils 1, transitionals 1. After aspiration of the shoulder joint, the child improved and one month later was still cyanotic, though the shoulder swelling had subsided. Cultures of the blood and of the nasal secretion at this time gave negative results.

Moon[12] has reported an anaerobic, strictly hemophilic diplobacillus isolated from an infected ethmoidal sinus. It differs from the Pfeiffer's bacillus as follows: It is larger; it is a diplobacillus; it gives more involution forms; it stains more readily and is anaerobic. It was found within the leukocytes in large numbers. It was specifically agglutinated by the patient's serum in dilutions of 16:1, and the opsonic index was 3. It was non-pathogenic for animals.

The hemoglobinophilic bacilli are interesting in that they are pure parasites, for the very evident reason that only in animals can they find the hemoglobin which, so far as we know, is absolutely necessary for their existence. And since they are not spore formers and are all very delicate organisms, their length of life outside the animal body is very short, probably a few days at the most.

The rather remarkable and extreme adaptation which they have undergone in relation to hemoglobin is also an interesting and important biologic phenomenon. While hemoglobin seems indispensable to them, certain closely related respiratory pigments, for example, hemocyanin and hemerythrin, which occur in some of the lower animals and appear to have a function similar to hemoglobin in the higher forms, cannot be utilized.

The exact rôle of hemoglobin in their metabolism is not known. They seem to be able to use about equally well this substance from nearly all higher forms of animal life, though the hemoglobin from the pigeon seems as a rule to give somewhat more abundant growth. It is doubtful whether the hemoglobin is necessary on account of its nutritive properties, because an extremely minute quantity (1 part in 80,000 parts of the medium) suffices for growth, and also because these organisms will not multiply at all when placed in distilled water containing small amounts of hemoglobin. The phenomenon may be therefore a catalytic one.

SUMMARY

The hemoglobinophilic bacteria may be divided into two general groups: (1) those of the Pfeiffer-bacillus type, all of which reveal the phenomenon of symbiosis and are very commonly found in infectious diseases; (2) a far more heterogeneous group which includes the organism described by Friedberger, the bacillus found by myself and by Koch in urinary and uterus infections, the bacillus found in the pus of the shoulder abscess previously referred to and also such organisms as have been described by Moon and some others. The first group is no doubt a very definite one, the members of which are closely related; indeed, usually practically identical. The second group comprises bacteria very different in character and remotely related to each other, having in common little more perhaps than the hemoglobinophilic property. Compared with the bacilli of the first group they are rare.

The hemophilic bacilli of Pfeiffer's type are of primary importance as secondary invaders in many infectious diseases, especially those involving the respiratory tract. As such, they are not harmless parasites, as has been shown by animal experimentation. In this respect they are about as common and often, perhaps, as important as such organisms as streptococci and pneumococci.

That they may be highly virulent at times and the cause of serious primary infections, is clearly shown in the not uncommon cases of purulent meningitis caused by these organisms.

Whether or not Pfeiffer's bacillus was the cause of the pandemic of influenza of 1889-1890, or is ever the cause of epidemics of influenza, is still a doubtful question.

Epidemics of clinical influenza occurring in recent years have been caused by a variety of organisms, including streptococci, pneumococci, *Micrococcus catarrhalis* and possibly other varieties.

Traveling Consumptives.—Few people with tuberculosis who travel exercise any precautions whatever. Beneficiaries of the three Government sanatoria are provided with pocket sputum cups, a colored 5 per cent. phenol, or other disinfectant solution, and are properly instructed. Others, particularly those who have resided at sanatoria, give some thought to their neighbors, but the vast majority of consumptives, as well as healthy persons, are careless with their sputa.—Ernest A. Sweet, *Public Health Reports*, April 9, 1915.

THE YOUNG GRADUATE AND THE PROPRIETARY MEDICINE QUESTION *

CARY EGGLESTON, M.D.
NEW YORK

The time has now arrived when you will go forth into the world at large to practice the profession to the study of which you have devoted these last four years. You all look forward to this as a time of release from the burdens of an academic life, and most of you probably anticipate it as the coming of your era of independence. I fear that those of you who cherish this idea without great restriction are destined to receive more than one rude shock within the first brief year. Within these walls your way has been pointed out to you by those who have learned the road by experience, and to them you have been able to turn for aid in the solution of the problems which have confronted you thus far. With the hour of your entrance into the practice of medicine, all of this will change, and it is you who will be sought out for advice and the solution of problems. Where these problems have to do with the diagnosis and treatment of human ills we have no fear that you will not solve them readily and, for the most part, with an ever-increasing skill. But other problems will confront you almost from the moment when you acquire your telephone number and place your nice new name plate out to face the weather.

Of these other problems and vexations, one which is destined to pursue you most relentlessly is that of the proprietary medicine and the "new and elegant pharmaceutic preparation" "nicely designed to suit all of your requirements." It is of this problem that I wish to speak a few words, and for the meeting of which I wish to prepare you in some measure.

PROBLEM OF THE PROPRIETARY MEDICINE

The chances are about even that among the first to ring your door bell will be a well-dressed gentleman carrying a small satchel who, without giving his name or stating his business, will so impress every one that he will gain admittance to your office at once. You will encounter in him a skilful and plausible talker who will endeavor to persuade you, for example, that for all pulmonary conditions you will find X-Y Company's scientific synthetic preparation decidedly superior to the older remedies. He will tell you of its advantages, will cleverly seek to implant the idea that it is quite without danger, that it is, of course, free from the many disadvantages possessed by all other preparations, including those in the "antiquated" pharmacopeia, and best of all, that it is in a form which is very pleasant to the patient and the doses and precise indications are stated in the neat little pocket companion which he will be glad to have you accept. Before he leaves you will begin to wonder why no mention was made of this truly remarkable new synthetic back in medical college. To make his case the stronger he will relate the names of several prominent hospitals in which it has now replaced the older drugs, and will casually call attention to the fact that Dr. Smith, who is the best-known man in your neighborhood, is using it in his practice with great success. All possible changes will be rung on this form of exploitation, and you will be bombarded on all sides by detail men, personal letters, beautifully gotten up booklets, card indexes, prescription pads and books, samples, circulars, wall charts, pencils, hosts of blotters, paper cutters, calendars, telephone pads, etc., each designed to induce you to use some particular preparation which has every conceivable advantage, with no disadvantage whatever. You will open your medical journal and be confronted with page after page of cleverly worded advertisements of the same preparations. Now and then a reprint will be sent you in a plain envelope of a paper by some unknown doctor with many titles and apparent hospital appointments whose name you could probably not find in the medical directory. But worst of all will be the time when one of your patients asks you what you think of "Laxaprune" or some other nostrum of that ilk for constipation.

A few of the preparations thus brought to your attention will be of some value and will not be frauds, but will be honestly offered and in some instances will be real additions to your therapeutic armamentarium. Others may be honest in their composition but will merely be nice mixtures of common pharmacopeial or National Formulary preparations, no better than you should be able to prescribe extemporaneously, but offered with some claims of advantage. Another group will comprise preparations perhaps not vicious in themselves, but made so by the exaggerated and false claims made for them. And the last group will be that of the utter frauds which are often not of the same composition two years in succession, although their claims never change with the alterations in their composition.

The problem which will confront you in this whole matter of the new synthetic, the specialty, the proprietary preparation and the nostrum will be for you to determine which is of value, the limitations of its advantages, and what dangers and disadvantages it has; which is merely a mixture such as any pharmacist could prepare on your prescription, and which are pure frauds. How are you to solve this problem? Have you the knowledge requisite for its solution? If you have the knowledge have you the time and the facilities at hand? Where shall you turn for trustworthy information? The first of these questions I will answer in a word or two, but to the last I shall devote some time, for it is your most important and readiest means available.

Have you the knowledge for the solution of this question in a given case? Yes, in many instances you have. Often the fraud is so patent and the claims are so preposterous and palpably impossible that a brief reflection will suffice to show you the worthlessness of the preparation. But in other instances there may be room for reasonable doubt, and the scrutiny to which you can submit the preparation will be inadequate to warrant a final judgment. You must here seek the aid of the unbiased opinions of others whom you can trust. This will also be true in those cases in which you could answer the question for yourselves, but for which you have neither the time nor the facilities.

NEW AND NONOFFICIAL REMEDIES

This leaves for discussion the question of where you shall turn for the desired trustworthy information. So short a time as ten years ago you would have been

---

* Address to the graduating class of Cornell University Medical College, 1915.

without such aid; but you who graduate now all have the desired source of information at your command. It is the volume entitled New and Nonofficial Remedies, published annually by the Americal Medical Association. That you may better understand the service this volume can render you I shall devote a few minutes to a brief review of its history and shall tell you something of the Council on Pharmacy and Chemistry, its work and the rules which govern its decisions on the characters and claims of the many preparations which are included in the volume. I shall also speak of the scope and limitations of the book and shall call your attention to some of the other work of the Council on Pharmacy and Chemistry which will prove of value to you in this same connection.

From the earliest days of therapeutics there have been frequent attempts made to commercialize various drugs and preparations, such common agents as ipecac, cinchona and veratrum viride long being thus exploited under the cover of secrecy. Then came the development of the complex mixture offered for the cure of a host of diseases and conditions, this rapidly developing into the common "patent medicine," which is still with us in untold numbers. As chemistry advanced within the past generation or so, there came the development of synthetic substances, some of which were found to have pharmacologic actions of more or less value.

The financial harvest reaped by the manufacturers of a few of these preparations, both synthetic and of the nature of common secret mixtures, naturally led many to turn their attention to the development of other preparations. It was soon appreciated by shrewd but unscrupulous persons that the liberal use of money for advertising would carry many preparations into wide use wholly without regard to any inherent value, or lack of value, which might be theirs. Secrecy and plausible praises were all that were necessary if combined with sufficiently wide and insistent advertising. Thus there sprang up in a night, like mushrooms, scores of simple mixtures of well-known substances under the guise of new synthetics, and hosts of worthless and even dangerous preparations. It was also discovered that physicians were, alas, quite as gullible as laymen, and there began a disgraceful exploitation of the medical profession which had reached such magnitude a few years ago that certain of the better informed members of the medical profession saw the need for a serious attempt to stem this tide for the good both of their profession and of the laity. This attempt finally took definite form in 1905, and in February of that year the American Medical Association created the Council on Pharmacy and Chemistry.

The Council on Pharmacy and Chemistry, or, as I shall speak of it, "the Council," is not a self-appointed committee of reformers, as some of its calumniators are fond of stating. It is a group of chemists, pharmacists, pharmacologists and physicians chosen for their ability to judge of the value of remedial agents, a certain number being elected annually by the Trustees of the American Medical Association. Their interest is the protection of the medical profession and the laity against fraud, secrecy and the undesirable advertising of proprietary remedies, and such as are not official in the pharmacopeia or National Formulary. It is their duty to examine into the validity of the claims made regarding new preparations, to record standards for their composition and to see that they are advertised in a way consistent with the truth regarding their value. To guide them in their decisions, it was necessary for the Council to establish certain rules with which each preparation should be required to comply before it could be admitted to the list of remedies which are honestly marketed and for which there is just evidence of some value. The preparations and remedies which meet all of the requirements laid down are said to be "accepted" by the Council for inclusion and description in its annual publication, New and Nonofficial Remedies. Their acceptance and inclusion in N. N. R. in no way implies any recommendation by the Council respecting their value. It merely indicates that they do not conflict with the published rules of the Council.

There are ten of these official rules laid down by the Council to govern the admission of any proprietary article to the book and, although these are given in full in the volume, together with some explanatory comments on them, I will take them up briefly for discussion, mainly to show how they serve to protect you against fraud and deception.

THE TEN RULES OF THE COUNCIL

Rule 1 requires that the composition of each preparation submitted for consideration shall be furnished to the Council for publication. When the substance is simple, its scientific name and chemical formula, if the latter is known, are required. In the case of mixtures, the amount of each active ingredient in a given quantity of the preparation must be stated, along with the general composition of the vehicle, including the percentage of alcohol which it contains and the identity of any preservatives which may be present. These data are published for each accepted article in the description given of it in N. N. R. You can, therefore, easily determine the precise nature of any such new preparation or drug by reference to this volume. You will then be in a position, in the case of many drugs and preparations at least, to judge for yourselves on the basis of your pharmacologic and therapeutic knowledge whether or not a given substance may be suited for use in a particular case.

Rule 2 requires that suitable tests for the determination of the composition, identity and purity of any preparation submitted shall be supplied and, in the case of mixtures, for the determination of the amount and activity of their potent ingredients. This rule is rather of indirect value to you, for you will seldom have either desire or opportunities to carry out the tests given. But it affords you the security of knowing that there are such tests to insure the identity and uniformity of the preparation as well as its activity. The fact that they are made public alone goes a long way toward insuring that the article as marketed is always the same. In addition, the Council applies such tests from time to time to samples obtained in the open market, and if they are found wanting in any respect, the manufacturers are warned of this fact, with the understanding that a failure to correct it may lead to the exclusion of the article from the list of accepted drugs.

Rule 3 calls for the rejection of all preparations which are advertised directly to the public. To this rule, however, there are two exceptions. The first permits the advertisement of disinfectants and germicides if this is restricted to "conservative recommendations for their use as prophylactic applications to superficial cuts and abrasions of the skin and to the mucous surfaces of the mouth, pharynx and nose." The second exception allows the advertising in an unobjectionable manner of nonmedicinal food preparations. This rule is of great value to the public. But it is not less so to you, for those who have worthy preparations are usually very desirous of having them included in N. N. R., and the mere fact that you may see a preparation advertised to the general public stamps it at once as one which is excluded from recognition by the Council and one which is in all probability in some respect fraudulent or else worthless.

Rule 4 serves to extend the scope of Rule 3 in preventing indirect advertising to the layman by for[illegible] to any preparation of which the label, package or enclosed circular contains the names of the diseases or conditions for which it is recommended. This guards you against becoming the unwilling agent of the manufacturer by placing in a patient's hands information which might lead him to self-medication with the particular preparation. This method of using the physician to advertise a proprietary medicine has been very greatly abused in the past, and its correction is a matter of much relief to the conscientious physician.

Rule 5 covers the question of false claims as to the origin of the material from which the preparation is made, and requires in addition that the name of the actual manufacturer must be furnished to the Council. The need for this rule may not be apparent to you at first, but when I mention that only a few years ago there were many persons engaged in the "patent medicine" business who were offering worthless or harmful mixtures under catchy names, often claiming that they were new synthetic drugs, and that often these persons merely engaged some pharmaceutic house to prepare these mixtures, which they then sold at fabulous prices, you will readily see how great an abuse this form of fraud could become. It had, in fact, become one of the greatest of all abuses in the field of proprietaries. Such mixtures of acetanilid, caffein and sodium bicarbonate as "antikamnia" were for years thought by many physicians to be true synthetics for which they would make their patients pay fancy prices on account of their own ignorance.

Rule 6 refuses admission to N. N. R. of any preparation for which exaggerated, unwarranted or misleading therapeutic claims are made. A reasonable degree of optimism is permitted the manufacturer, but this is never allowed by the Council to be carried beyond proper bounds. It used to be the practice of almost every manufacturer of a new drug to make the most extravagant claims regarding its value, all mention of any of its disadvantages being scrupulously avoided. Under Rule 6 of the Council, the claims for many articles have been so greatly modified that there is little left to recommend them, but the physician is in a far better position to determine whether or not they may be of service to him.

The seventh rule guards against possible accident by requiring the principal label on any article which contains potent or poisonous substances to bear a statement of the amount of such substances in a given quantity of the preparation.

Rule 8 calls for the naming of a preparation in a manner which shall be sufficiently descriptive of its composition, either chemical or pharmaceutic. It also refuses recognition to such articles as bear objectionably suggestive names, or such as imply the diseases or conditions for which the preparation is recommended.

A further means of protection against fraud is provided by Rule 9, which requires that the patent numbers, or those of the registered or copyrighted names, shall be supplied to the Council, and that a copy of the protected label of the preparation shall be filed with the Council.

Lastly, Rule 10 rejects all mixtures which are either unscientific or useless, or which are "inimical to the best interests of the public or of the medical profession."

OTHER CONSIDERATIONS

From what has gone before, I think that you must now have some idea of one of the difficulties which will confront you as practitioners, and I hope that you will also see and appreciate the value of the help which is given you in the solution of this difficulty by the work of the Council on Pharmacy and Chemistry which has led to the preparation of N. N. R. This is not, however, the only service which the Council is rendering. Certain of the worst frauds which are being perpetrated from time to time on the medical profession are being run down, and accounts of them appear every little while in The Journal of the American Medical Asociation. A volume is also published annually, in which will be found the reports of the Council on those preparations which have been refused acceptance for inclusion in N. N. R., and the reasons for their rejection are there clearly set forth.

The question will arise in your minds as to what you are to do when you find that a certain preparation is not mentioned in the latest volume of N. N. R. In general, you may feel fairly certain that if it is not mentioned it is because it is not acceptable on account of conflict with one or more of the rules just mentioned. It is, of course, not possible for the Council to examine into the claims of every new preparation, but it should be said that it has so far covered nearly, if not quite all of those preparations which have any genuine claim for consideration. Such, therefore, as are not to be found in N. N. R. may be presumed to be offenders in some respects, unless, of course, they have been too recently introduced to have come under consideration. (An inquiry sent to the secretary of the Council will disclose the status of any article.)

In addition to the facts which I have already brought out concerning the material in N. N. R., I would also call your attention to certain concise discussions given in it on the pharmacology, pharmacy and toxicology of various classes of preparations. The limits of dosage and the information which will enable you to combine the new preparations in suitable prescriptions are likewise to be found in this volume.

Today, upon the eve of your graduation into the practice of medicine, I have taken this occasion to tell you something of the potential value which the book New and Nonofficial Remedies holds for each of you. I hope that you will all make constant use of it; that you will learn that it is an honest and unbiased adviser ever at your hand; and I feel sure if you do call on it for help as frequently as the occasions may arise that you will come to think that I have done it but poor justice in my attempts to show you something of its inestimable value.

414 East Twenty-Sixth Street.

THE ONSET OF HUNGER IN INFANTS AFTER FEEDING

A CONTRIBUTION TO THE PHYSIOLOGY OF THE STOMACH *

H. GINSBURG, B.S., I. TUMPOWSKY, B.S.
AND
A. J. CARLSON, Ph.D.
CHICAGO

Pediatricians differ as to the incidence of hunger in infants, because up to the last few years there has been no certain objective criterion for the existence of hunger. This has led to varying views and practices in regard to the frequency with which infants should be nursed. Those favoring the two-hour interval for the first month are Budin, Burnet, Chapin, Cotton, Dodson, Fowler, Heubner, Holt, Rachford and Webster. Ahlfeld, Kerley and Koplik advocate two and one-half to three hour feedings. Among exponents of the three-hour interval are DeLee, Feer, Finkelstein, Lamb, Langstein, Meyer, von Pirquet and Williams. Abt believes in a three-hour to four-hour interval; while Brenneman, Czerny, Grulee, Jascke and Keller designate four-hour periods.

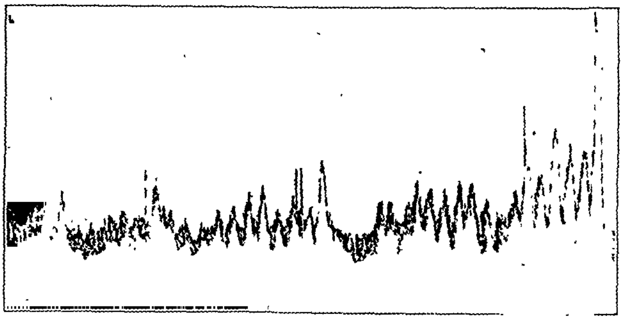

Fig. 1.—Infant, 14 days old, finished nursing at 9:05 a. m.; beginning of gastric hunger contractions 11:10 a. m. (chloroform manometer).

It is now established that the subjective sensation of hunger is caused by a certain type of contraction of the fundal end of the empty stomach stimulating sensory nerves in the wall of the stomach.[1]

Since the contractions peculiar to the cardiac and fundal ends of the empty stomach are, in normal individuals at least, an objective index of hunger, the balloon method may enable one to determine the time of onset of hunger in infants after previous feeding, and the answer to this question may aid in fixing the time that should elapse between the nursings of normal infants.

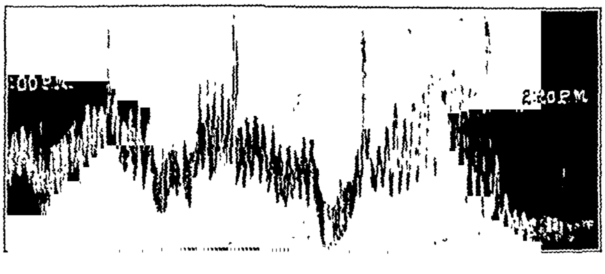

Fig. 2.—Infant, 4 days old, finished nursing at 11:50 a. m. Tracing shows end of period of gastric hunger contractions at 2:30 p. m. (chloroform manometer).

METHOD AND RESULTS

The experimental procedure is recorded in a previous publication.[2] The observations were made on thirty normal infants, from 24 hours to 4 weeks old. Introduction of the balloon into the stomach directly after nursing leads to vomiting of the balloon and some of the food. The balloon is readily retained from forty-five minutes to one hour after feeding. The accompanying tracings were obtained from infants who were asleep or otherwise quiet, since inhibition of the hunger contractions results when the child is restless.

Fifty-five observations were made on thirty infants. The average time between nursing and the appearance of the period of hunger contractions was two hours and forty minutes, with a maximum of three hours and thirty minutes, and a minimum of two hours and twenty minutes.

Our tracings show that when the stomach is full of food the inflated balloon in the fundus reveals practically no contractions. As the stomach gradually empties, feeble tonus contractions appear, and increase in rate and intensity until they end in a period of typical hunger contractions from two and a half to three hours after the previous nursing. This change of the tonus contractions of the fundic end of the stomach partly filled with food into the hunger contractions of the empty stomach have already been demonstrated for the adult by Rogers and Hardt.[3] Pisek and Le Wald[4] have shown by roentgenogram experiments that "three hours is practically the emptying time of a child's stomach and often less than that." Czerny,[5] Leo[6] and Pipping[7] conclude that the stomach of a normal infant empties itself in from about one and a half to two hours. The time required for emptying of the stomach depends, of course, on the quantity of the food as well as on the rate of the gastric secretion and the vigor of the gastric digestion peristalsis.

In this connection it may be of interest to note that the mammalian infant, except when under the strict control of a pediatrician, feeds, on the whole, as soon as the hunger sensation is strong enough to be uncomfortable, provided food is at hand, and he thrives on this procedure; while the infant whose routine is ordered by the pediatrician nurses every two, three or four hours, irrespective of the onset or intensity of the periods of hunger. Of course, a certain period of rest for the gastric glands may be beneficial.

SUMMARY

The infant's stomach shows feeble tonus contractions of the fundal end, one hour after nursing. As the stomach discharges its contents these tonus undulations gradually increase in frequency and intensity until by the end of from two and a half to three hours these become transformed into vigorous hunger contractions. The time of onset of hunger contractions after

the previous feeding varies for each infant. In our present series the minimum is two hours and the maximum three hours. The hunger contractions of the empty stomach are modified tonus waves of the fundus of the digesting stomach, as shown by Rogers and Hardt.

In the normal individual the presence of vigorous hunger contractions is probably a biologic evidence that the stomach is in proper condition to receive food. If this is the case, the stomach of a normal infant is ready to receive food from two to three hours after the previous nursing.

OVARIAN TRANSPLANTATION *

C. C. GUTHRIE, M.D.
AND
M. E. LEE
PITTSBURGH

Transplantation of human ovarian tissue with varying degrees of success has been reported and is occasionally practiced. For the most part the operation has been performed with a view of preservation of its internal secretory function. Many case histories have been reported which indicate that in this way the operation is frequently successful. In 1906 Morris[1] reported the birth of a child in a woman from whom the ovaries were removed and in whom ovaries from another woman were engrafted four years previously.

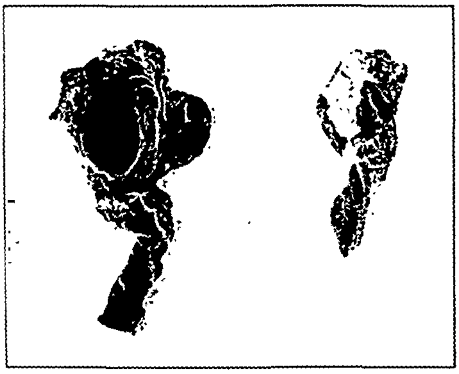

Fig. 1.—Engrafted ovaries, natural size.

For general biologic reasons, but particularly with the view of studying heredity, numerous attempts have been made to engraft ovarian tissue into animals and birds. Prior to 1894, Romanes[2] made many experiments in endeavoring to transplant ovaries in rabbits and dogs. His results were uniformly unsuccessful.

Gregorieff[3] in 1897 reported pregnancy in four rabbits from which the ovaries were removed and replaced.

Magnus[4] in 1907 reported the birth of young by a black rabbit whose ovaries had been removed and replaced with those from a white rabbit. The coat markings of the young indicated a soma or foster-mother influence.

Guthrie[5] in 1907 successfully transplanted ovaries from hen to hen. Such fowls laid eggs which were hatched. Chicks thus obtained showed evidence of foster-mother influence.

From experiments on rats, Marshall and Jolly[6] in 1908 stated that (1) ovarian autografts succeed better in the kidney than in the peritoneal cavity; (2) ovarian isografts succeed less readily than autografts; (3) isografts are more successful between nearly related than between distantly related individuals, and (4) it is not necessary to create a deficiency—that is, remove ovarian tissue—in order to achieve such success. Their work was largely based on preservation of histologic structure in transplanted tissue.

Ribbert[7] in 1898 reported preservation of structure in guinea-pig ovarian tissue removed and replaced.

Castle[8] and Guthrie[9] in 1909 obtained young from guinea-pigs whose ovaries had been removed and replaced with ovaries from other guinea-pigs.

The results reported in this paper were obtained on dogs.

Two sister puppies 3 months old were operated on, the ovaries in each case being removed and transplanted into the other animal. At this time the organs measured about 6 mm. in length. The animals were operated on simultaneously. Each ovary was exposed and its pedicle firmly grasped throughout its entire extent by curved forceps. A fine silk thread was then passed through the base of the ovary by means of a cambric needle. The ovary was then completely separated from the pedicle with a knife. It was then instantly transferred to the other animal and fastened to the pedicle of the former ovary by means of the thread previously inserted into its base.

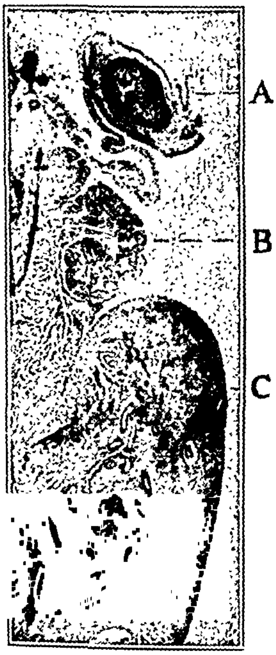

Fig. 2.—Low power photomicrograph, showing free relation of transplanted ovary to fallopian tube; *A*, fallopian tube; *B*, fimbriated extremity of fallopian tube; *C*, ovary.

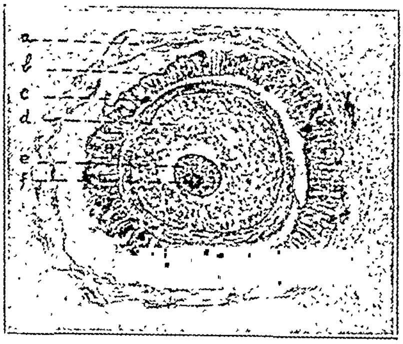

Fig. 3.—Camera lucida drawing of graafian follicle in right engrafted ovary; the structures are all normal in appearance; *a*, theca folliculum; *b*, corona radiata; *c*, zona pellucida; *d*, ova; *e*, germinal vesicle; *f*, germinal spot. Schron's granules were observed.

The animals made uneventful recoveries and appeared the same as dogs not operated on. One was lost, while the other was killed through accident eighteen months after operation. The animal was in good condition.

[9] Guthrie: Science, 1909, xxx, 724.

There were slight peritoneal adhesions between the intestines and the anterior wall of the abdominal cavity at one point along the line of incision. The right ovary appeared normal and was much larger than at the time of transplantation (Fig. 1). It was whitish pink and showed a few dark spots. The left ovary was represented by a cystlike mass the size of a navy bean. It was dark in color and soft to the touch. When the capsule, which was markedly thickened, was opened, a small gelatinous mass was found. It was clear to pale yellow, and measured about 10 by 4 by 2 mm.

The lumen of the upper end of the right fallopian tube appeared to be somewhat narrowed. Communication between the fimbriated extremity and the ovary was unobstructed (Fig. 2). The lumen of the left fallopian tube was patent.

Histologic examination of the right ovary revealed abundant normal histologic elements (Fig. 3), including corpora luteum (Fig. 4). The left ovary had undergone complete colloidal degeneration, at least so far as the reproductive elements were concerned.

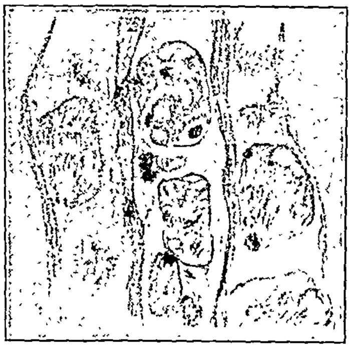

Fig. 4.—Camera lucida drawing of a few cells of a corpus luteum in the right engrafted ovary.

As no attempt at mating the animal was made, the experiment is not conclusive as to the possibility of pregnancy.

The result leads us to believe that ovarian transplantation in dogs is not only feasible but also offers a promising means of obtaining information regarding optimum conditions for success as well as heredity.

SYPHILIS OF THE STOMACH

A REPORT OF EIGHT CASES WITH ROENTGENOLOGIC FINDINGS *

WILLIAM A. DOWNES, M.D.
AND
LEON T. LE WALD, M.D.
NEW YORK

It is generally stated in textbooks on diseases of the stomach that syphilis of this organ is of rare occurrence, and that it is found in scarcely more than 1 per cent. of patients afflicted with the disease. The advent of routine blood examinations, however, and the great advance made in the diagnosis of all gastro-intestinal lesions by the use of the Roentgen ray prove that this contention can no longer be held.

Since June 1, 1913, eight cases of syphilis of the stomach, in which the diagnosis was established with a fair degree of certainty, have been admitted to the ward service of St. Luke's Hospital. Five of these patients suffered from the symptoms of obstruction, and according to the assignment of cases by region, in effect since that date, were referred to one of us (W. A. D.) for operation. The other three were cared for in the medical service, as no indication for surgical intervention existed at the time.

Syphilis appears in the stomach as a late manifestation of the disease in both the congenital and the acquired types. Jerome Meyers[1] states that the age in the youngest recorded case of the acquired form is 18 and the oldest 60. In the congenital cases, gummas have frequently been found at necropsy in the stomach of the new-born.

The ages in our cases were 14 and 17 in the congenital type and 22, 23, 34, 42, 62 and 63 in the acquired.

Diffuse syphilitic gastritis has been described, and histologic examination in such cases has shown the changes of generalized gummatous infiltration of the submucosa. In the great majority of instances, however, the disease appears in the form of localized gummas, either single or multiple. The lesions may be situated in any part of the stomach, but seem to occur most frequently in the pars pylorica, involving either the lesser or greater curvatures, or both. The gummatous deposits are described by pathologists as starting in the submucosa and spreading gradually to the other coats. These deposits pass through the stages of infiltration, ulceration and cicatrization, in varying degrees. One portion of the wall may remain infiltrated while another passes on to ulceration or may become cicatricial. Definite pyloric stenosis may occur either as a result of the gummatous infiltration, cicatrization of the ulcer or perigastric adhesions. Obstruction from the combination of these conditions necessitated operation in five of our cases. Besides the lesions in the stomach wall, other syphilitic manifestations are usually present, such as marked perigastric adhesions, changes in the liver capsule and gummas of the liver, and extensive involvement of the gastrohepatic and gastrocolic lymph glands, as well as other constitutional and local evidences of the disease.

The symptoms of gastric lues when considered in a general way differ very little from those of other lesions of the stomach of equal extent and like location; but when carefully analyzed, several striking differences become apparent. To begin with, the pain lacks the periodicity of the average simple ulcer—it is not so much influenced by the taking of food and is frequently referred to as gnawing in character; it is, however, persistent, and was an important symptom in the cases observed by us. Vomiting was a marked symptom in our cases almost from the beginning. This is probably accounted for early, by the gummatous infiltration, and later on, by the cicatrization and adhesions, possibly too, indirectly from the disturbed liver function. Although small quantities of blood have been found in the gastric analyses of the cases, and a few claim to have had tarry stools, hemorrhage has not been so frequent or severe as in simple ulcer; this is especially striking when the long history of many of the cases is taken into consideration. Our observation in this respect corresponds with the experience of Fenwick,[2] who states

[1] Meyers, Jerome: Albany Med. Ann., October, 1912.

[2] Fenwick, and Soltau, W. S.: Cancer and Other Tumors of the Stomach, Philadelphia, P. Blakiston, Son & Co., 1902, p. 313.

that the infrequency of hematemesis in these cases helps to differentiate them from simple ulcers. On the other hand, Lockwood[3] reports a fatal case from hemorrhage. The predominating feature of the disease clinically is the extreme loss in weight, which in one of the cases here reported amounted in eighteen months to one half of the patient's former weight.

Gastric analysis was omitted in Case 5, on account of constant vomiting and disinclination on the part of the patient. In Case 6, there is no record that an analysis was made. In Cases 1, 7 and 8, the examination showed absence of free hydrochloric acid and a combined acidity of 32, 16 and 14, respectively. In these cases there was extensive involvement of the stomach wall as shown by the roentgenograms and in Case 1 by operation. In Cases 2 and 3, in which the symptoms were those of pyloric stenosis and the lesions were demonstrated at operation to be at the pylorus, free hydrochloric acid was 30 and 36, with a combined acidity of 52 and 70; while in Case 4, in which there was hour-glass contraction with constriction at the pylorus, the analysis showed free hydrochloric acid 13, total acidity 34. Lactic acid was absent in every case. The guaiac test for blood was positive in five cases. While these findings are in no wise conclusive, they would seem to suggest that there is absence of free hydrochloric acid, and a low total acidity in the cases, with extensive involvement of the gastric mucosa unaccompanied by special involvement of the pylorus, and that the distinctive pyloric stenosis type without diffuse infiltration of the mucosa shows the usual findings of ulcer in that region.

The diagnosis of gastric syphilis can be established without much doubt if the history and clinical findings are given proper consideration. In the congenital cases, the family history and the early history of the patient, his general development and appearance and other syphilitic stigmata with symptoms of gastric disturbance are very suggestive, while in the acquired cases a definite history of infection may be established. In both instances, the course of the disease differs from the simple type of ulcer, in that it is influenced but little by dieting and the ordinary methods of treatment, and it is unlike malignancy in that there is not the steady and continuous progress to a fatal termination. With such a history and due consideration given to the symptoms previously enumerated, the added evidence of a positive Wassermann reaction and the roentgenographic findings of deformity of the stomach make the diagnosis practically certain. Finally, the value of the therapeutic test must be given due weight. That mixed treatment and salvarsan will produce temporary improvement in old ulcers or even certain cancer cases there is no doubt, but the benefit is of short duration, where, as in the class of cases under consideration, there is a return to normal health; and if the lesion in the stomach has not reached the cicatricial stage, this organ may be restored to its former condition.

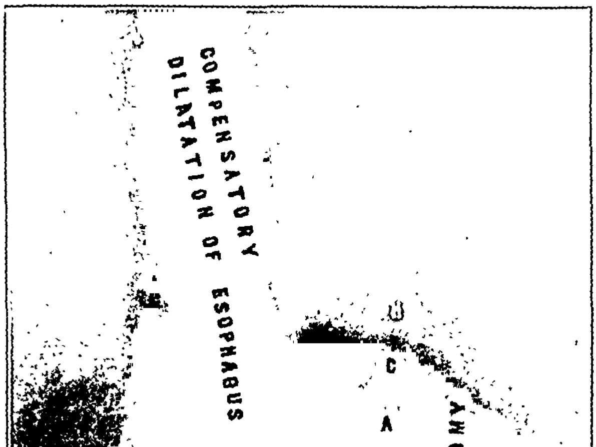

Fig. 1 (Case 1).—Girl, aged 14. Note dumb-bell-like appearance due to sclerosis of body of stomach. After gastro-enterostomy, most of food going through opening, but enough passing through stenosed portion to outline it. Note compensatory dilatation of esophagus.

Two of our cases were of the congenital type, two gave definite histories of chancre and in one the husband gave a positive Wassermann. The history as to primary infection in the remaining three was negative. The Wassermann reaction was four plus positive in every case. Roentgenograms showed definite changes in the shape and size of the stomach in six cases, and in the other two demonstrated a marked degree of pyloric stenosis. The deformity in the stomachs varied from an irregularity along the curvatures to hour-glass contracture, and in one case to extreme distortion, giving the appearance not unlike that of a dumb-bell. Response to treatment has been astonishing in each case, and bears witness to the value of the therapeutic test.

The pathologic diagnosis of syphilis of the stomach is even more difficult to establish with certainty than the clinical diagnosis, as syphilitic infiltration so closely resembles tuberculosis. In two of our series, Cases 4 and 5, specimens were removed for microscopic examination. In Case 4 a nodule the size of an almond was removed from the surface of the liver, which was studded with such tumors varying in size from a pea to a walnut. Macroscopically, this was a typical syphilitic liver. Dr. Wood, pathologist to St. Luke's Hospital, did not feel justified in making a positive report of syphilis from the morphology.

A fair sized piece of gastric mucosa and an omental gland 1.5 by 0.6 cm. were removed from Case 5 for examination, and the report on the sections from the mucosa states that the diagnosis must remain in doubt with the probability that the condition is syphilis rather than tuberculosis. Sections of the gland showed simple inflammatory reaction. (For detailed pathologic report of these two cases, see histories.)

---

[3] Lockwood, G. R.: Diseases of the Stomach, Philadelphia, Lea and Febiger, 1913, p. 305.

Roentgen-ray findings in syphilis of the stomach may be divided into three classes: first, a fairly typical change consisting of a diminished size and dumb-bell-like appearance of the stomach due to deformity caused by infiltration involving the middle or pyloric half of the stomach, this portion representing the handle of the dumb-bell. In this type the pyloric sphincter may be involved and held open so that the stomach empties, or at least begins to empty in a very rapid manner, such as has been observed in carcinomatous infiltration of the pylorus where the pylorus is held open, or in spontaneous or artificial gastro-enterostomy. But even though the stomach begins to empty in a very rapid manner, there may be a trace of food remaining high up at the cardiac end at the sixth hour.

Secondly, the findings may be similar to those in the first type except that the involvement of the pylorus or the extreme stenosis of the infiltrated portion of the body of the stomach may cause delay in the emptying of the stomach such as occurs in ulcer or carcinoma.

In both the first and second types, however, the stomach appears to be smaller than normal, and there is apt to be a tendency to compensatory dilatation of the esophagus to make up for the diminished capacity of the stomach.

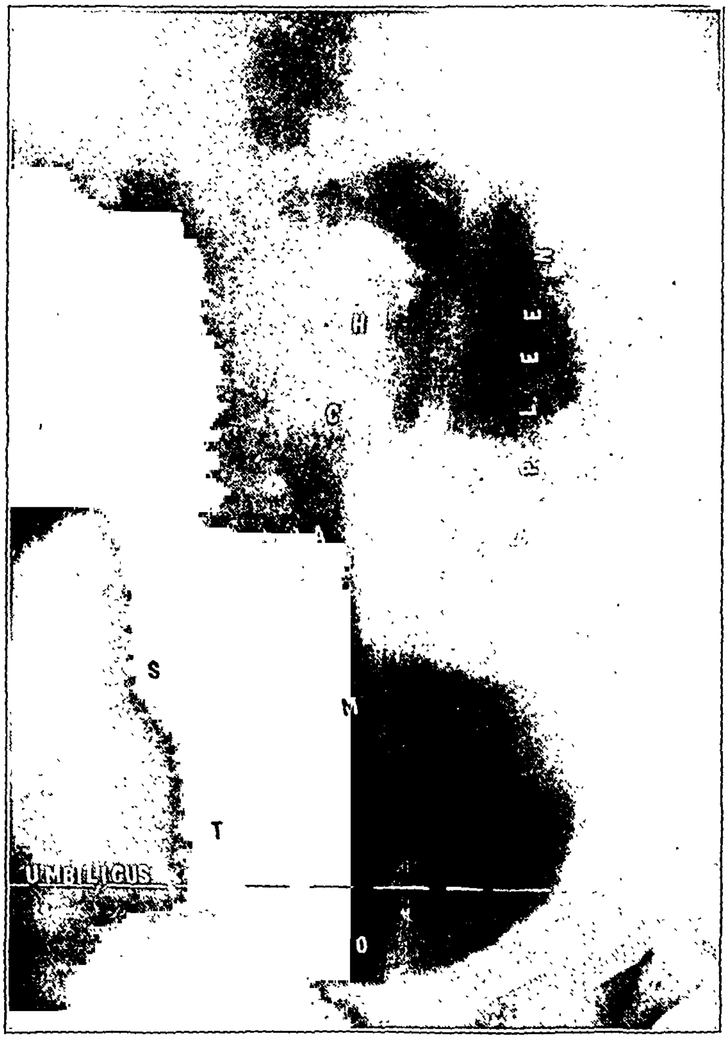

Fig. 2 (Case 4).—Woman, aged 34. Note hour-glass constriction with long channel between pouches. Condition confirmed at operation and relieved by breaking up of perigastric adhesions and performance of gastro-enterostomy to the lower pouch.

In the third type the infiltration may involve only the pyloric region, in which case the findings may resemble closely those found in cicatrized ulcer in this region and may be accompanied by dilatation of the stomach.

The treatment of gastric syphilis is, strictly speaking, medical; and if the diagnosis could be made while the disease is in the stage of infiltration, there should be no complications requiring operative intervention. Even though the pylorus is encroached on in the early stage, there is reason to believe, from the rapid response to proper treatment in nearly all reported cases, that stenosis of any extent or duration could be easily prevented. However, when ulceration and cicatrization have taken place, surgical measures play an extremely important rôle in the treatment of this condition, and should not be too long postponed. Three cases, 6, 7 and 8, showed little or no obstruction by Roentgen examination, and for this reason the question of operation was deferred until after vigorous antiluetic treatment had been given a trial. There was immediate response in each case, and now, from six to eighteen months later, all three patients are in good health. It will be noted from the histories of these patients that pain was the most prominent symptom, and not vomiting, as was the rule in the obstructed cases. Persistent vomiting with increasing loss of flesh and strength is by far the most frequent complication requiring operative relief. Gastro-enterostomy best meets the indication, and was the operation employed in five of the cases here reported. In three instances, involvement of the stomach wall was so extensive that it was difficult to find a fit place to make the anastomosis. Jejunostomy should be borne in mind, and would be preferable to a difficult gastro-enterostomy in a bad risk. Pylorectomy and the excision of ulcers are usually contraindicated on account of coexisting lesions. The former operation could have been performed in Case 2, but the presence of tabes seemed to be sufficient contraindication. In Case 3, also of the pyloric stenosis type, there was marked fixation to the liver and the man was in poor condition; but we so placed the anastomosis that a two stage operation could be undertaken. Improvement was so rapid and satisfactory that the patient refused a second operation. We are aware of the fact that all gastric ulcers, syphilitic or otherwise, have potential dangers, and for this reason the question of resection should be considered in every suitable case. If there is sufficient evidence, however, to make a diagnosis of syphilis of the stomach, no case should be subjected to more than the simplest form of operation necessary to relieve urgent symptoms until after antiluetic treatment has been given a reasonable trial.

SUMMARY

Syphilis of the stomach occurs much more frequently than was formerly supposed. The Wassermann reaction and roentgenologic examinations have provided the missing data necessary to establish the diagnosis. These aids to diagnosis should be applied in every case of disease of the stomach. If the diagnosis is made reasonably early, antiluetic treatment should control the symptoms; if not made until late in the disease, surgical intervention may become necessary to relieve complications.

REPORTS OF CASES

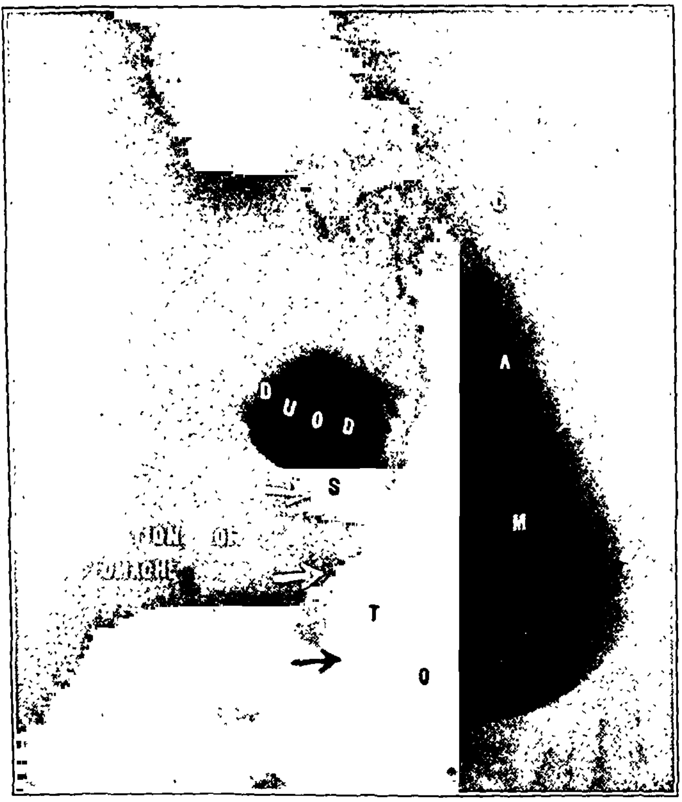

Fig. 3 (Case 5).—Woman, aged 23. Note deformity at pyloric third of stomach due to sclerosis. Note close resemblance to new growth. Diagnosis of syphilis confirmed by operation and microscopic examination of section of stomach wall. Symptoms relieved by gastro-enterostomy, but deformity persisted.

CASE 1.—*History*.—H. D., girl, aged 14, admitted to St. Luke's Hospital, June 10, 1913, whose father was living and whose mother had died of apoplexy, had never been strong; she had had more or less pain in stomach after eating as long as she could remember. For two years the eating of solid food had caused vomiting and severe pain; she lived on fluid diet six months and now swallowing of liquids caused pain and was frequently accompanied by vomiting; she never vomited blood. Examination revealed emaciated body with sallow skin; eyes negative; bad teeth; palpable glands in postcervical chains; lungs normal; heart showed a systolic murmur. Abdomen retracted, not tender on palpation, liver palpable 3 cm. below the costal margin; spleen enlarged. Extremities normal. Weight 52 pounds. Test meal showed free hydrochloric acid 0, total acidity 32, blood positive. Wassermann reaction four plus positive. Hemoglobin 50 per cent.

Roentgen Examination.—The food passed into the cardiac end of the stomach, which it soon filled, and then backed up into the esophagus; only a trace passed through a very long, narrow, stenosed portion of the stomach extending from the cardiac end to the pyloric region, where a slight pouch was then evident. This gave a peculiar dumb-bell-like appearance to the stomach outline—one portion of the dumb-bell being formed by the cardiac end and the other portion by the pyloric end with a long narrow handle part of the dumb-bell between. The patient was then studied carefully in various positions, and the deformity of the stomach found to be constant. The stomach failed to empty itself within six hours. The following day a confirmatory examination was undertaken, and showed that the peculiar deformity of the stomach persisted. The patient was then admitted to the hospital and a third examination was made of the stomach, which confirmed the finding of stenosis of the body of the stomach producing dumb-bell-shaped deformity. Syphilis of the stomach was suggested as a possible diagnosis from the Roentgen examination.

Operative Indication: Persistent vomiting due to deformed stomach.

Operation.—July 12, 1913, a posterior gastro-enterostomy to the cardiac pouch was done with considerable difficulty owing to adhesions and size of pouch. Recovery was uneventful; no vomiting occurred until the tenth day. This was due to taking food in too large quantities and was relieved by properly regulating feedings.

Pathologic Findings.—The middle half of the stomach is occupied by an infiltrated mass which has practically destroyed the lumen. The greater curvature is drawn up to the lesser. There is a small pyloric pouch which connects with a moderate-sized cardiac pouch by a long narrow channel into which a finger cannot be invaginated. At some points the wall is infiltrated and has a doughy feel, while other portions are hard and fibrous. The wall of both the cardiac and pyloric pouches is thickened. There are many perigastric adhesions. The liver is enlarged and grayish.

Two weeks after operation the patient was referred for Roentgen examination on account of vomiting. This examination showed that the gastro-enterostomy was working satisfactorily, but that the child was overtaxing the capacity of the stomach by taking too much food as she began to improve in health and appetite. It was plain to see from the Roentgen ray that food backed up into the esophagus owing to its being taken in greater quantities than the gastro-enterostomy could take care of (Fig. 1). Based on this examination, feeding in smaller quantities but at more frequent intervals was advised. Vomiting ceased and gain in weight followed. The patient was examined at intervals of several months up to the present time. The deformity of the stomach persisted, but the gastro-enterostomy worked perfectly, taking most of the food from the stomach; but gradually more of the food appeared to be going through the pylorus, suggesting that possibly some of the stenosis was being relieved by the antisyphilitic treatment. The constipation, which was a marked feature in the case before the operation, has been entirely relieved, and this is borne out by the passage of the bismuth meal through the colon in normal time. The last examination, made Feb. 11, 1915, one year eight months after gastro-enterostomy, showed that there was now very little tendency to backing up into the esophagus.

The patient was discharged July 17, 1913. On being examined Feb. 11, 1915, the patient was found to have gained 20 pounds in weight, was eating solid food, and was improved in every way.

CASE 4.—*History*.—G. R., widow, aged 34, admitted to St. Luke's Hospital, Jan. 4, 1915, had a negative previous history, two children and no miscarriages. Ten years ago she had a severe attack of epigastric pain with vomiting of blood; one year later she noted a swelling in the abdomen just to the right of the umbilicus. She had had attacks of pain in the upper abdomen from time to time which had no relation to the taking of food, usually radiating to the back and frequently requiring morphin; she had had attacks of vomiting at irregular intervals; the vomitus usually consisted of food recently taken and did not contain blood. One attack of jaundice occurred about five years ago. The swelling on the right side had increased in size until now she could feel a mass the size of an orange, not tender, and there was only occasional pain in this region. Her general appearance was that of a poorly nourished woman appearing many years older than the age given; color bad; eyes negative; heart and lungs normal. Liver edge palpable 1 cm. below the costal margin. In the right upper quadrant was a rounded tumor mass the size of an orange which moved with respiration, seemed to be attached to the liver, and was slightly tender. Reflexes normal. Weight 116 pounds. Wassermann reaction four plus positive. Tuberculin reaction negative. Fasting stomach showed 65 c.c. of greenish fluid containing mucus and strands, small particles of food and blood clots. Bile plus, lactic acid 0, free hydrochloric acid 13, total acidity 34.

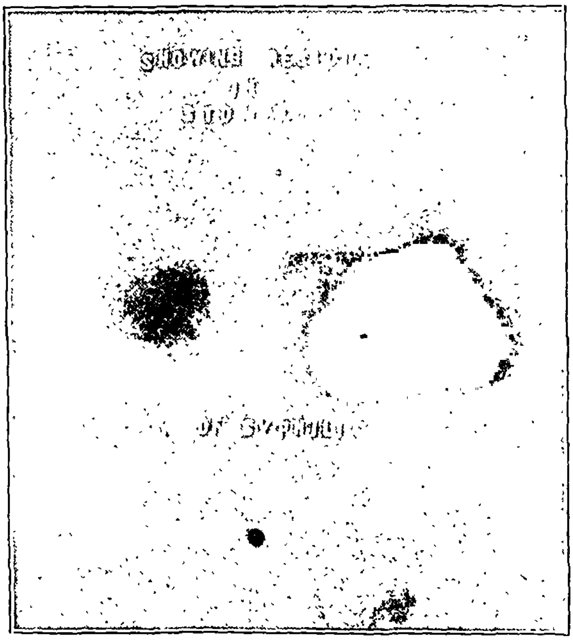

Fig. 4 (Case 6).—Boy, aged 17. Note deformity at junction of pyloric and middle thirds of stomach. This case responded to medical treatment, but the deformity remained.

Roentgen Examination.—This revealed the stomach as having the appearance of being deformed, of an hour-glass-like appearance. The lower pouch of the stomach appeared to be dilated and reached to a point 1 inch below the umbilicus, the upper half very much narrowed (Fig. 2). (There is a distinct shadow indicating an enlarged spleen.) The pyloric region appeared to be somewhat deformed, suggesting a spasmodic condition or *pressure*. At the sixth hour there was a large residue in the stomach, the shadow of which measured 4 by 3 inches. At the twenty-fourth hour there was still some bismuth remaining in the stomach.

Operative Indications: Hour-glass stomach with retention; abdominal tumor probably distended gallbladder.

Operation.—Jan. 13, 1915, a posterior gastro-enterostomy to distal pouch, cholecystectomy and division of perigastric adhesions was performed, with excision of the nodule from liver. As the cardiac pouch was small and difficult to expose, and the channel connecting the pouches sufficiently wide to admit three fingers, it seemed best to unite the intestine to the distal pouch.

Pathologic Findings.—The stomach was exposed with considerable difficulty, as it was adherent to the parietal peritoneum and the under surface of the left lobe of the liver. The anterior wall and greater curvature of the stomach showed an extensive cicatrix resulting from an ulcer which gave the appearance of having healed at one part and still being active at another.

The perigastric adhesions, together with the ulcer, had formed an hour-glass constriction, which was situated at the junction of the upper and middle thirds of the stomach. Division of the adhesions resulted in liberating the stomach to the extent that a channel was formed between the pouches which would admit three fingers. The pyloric end of the stomach was bound to the under surface of the right lobe of the liver by adhesions and would barely admit one finger. The gallbladder was distended to the size of a large pear; the cystic duct was occluded by a single stone; the liver was enlarged, the capsule thickened, containing many nodules varying in size from that of a pea to an English walnut.

Convalescence was straightforward. March 19, 1915, the patient had gained 20 pounds and felt well. Roentgen examination showed the gastro-enterostomy working satisfactorily, but the deformity of the stomach persisted.

Pathologic Report.—Sections from liver show marked degeneration and areas of necrosis of the parenchyma. There is marked general infiltration with round cells and many structures showing tuberclelike masses which contain giant cells of the Langhans type. There is moderate connective tissue proliferation, and occasional areas showing granulation tissue of the tuberculous type, with many endothelial cells and areas of caseation. Multinucleated giant cells are not found except in the tubercles. No tubercle bacilli are found in sections stained with carbolfuchsin, and no *Spirochaetae pallidae* in Levaditi preparations. The liver substance is almost entirely replaced by the growth, and the diagnosis must be left in doubt with the probability that the condition is syphilis rather than tuberculosis.

Case 5.—*History.*—F. G., woman, aged 23, admitted to St. Luke's Hospital, Jan. 15, 1915, had been married three years, and had one child, and no miscarriages. For the past eight months she had had an aching pain and sense of epigastric distress coming on immediately or within half an hour after eating, accompanied by nausea and sometimes vomiting, which relieved the pain. This pain radiated into the neck and toward the umbilicus. For the past two months she had vomited constantly; there was no blood in the vomitus or stools; the patient was hungry, but could not retain food. She had lost 22 pounds in the past eight months. Her general appearance was that of a poorly developed, emaciated woman. Palpable cervical lymph nodes; systolic murmur at the apex; right lung dull at apex. Breath sounds harsh and high-pitched, expiration prolonged. A few sibilant râles at base. Abdomen scaphoid and tender at costovertebral angles. Palpation showed a firm indefinite mass in the epigastrium above and to the left of the umbilicus. Knee jerks absent. Weight, 88 pounds. Wassermann reaction four plus positive. Tuberculin reaction negative. No report on gastric contents. Wassermann on husband showed four plus positive.

Roentgen Examination.—This revealed a peculiar break in the bismuth shadow at the pyloric end of the stomach; further examination showed the peculiar filling defect in the pyloric end of the stomach to be permanent, indicating some infiltration of the stomach wall very much as occurs in a new growth (Fig. 3). At the sixth hour there was a distinct residue in the stomach, the shadow of which measured 1½ inches in diameter. The filling defect still persisted in the pyloric end of the stomach, especially along the greater curvature. At the twenty-fourth hour there was a trace of bismuth still remaining in the stomach.

Operative Indications: Pyloric obstruction with persistent vomiting.

Operation.—Jan. 27, 1915, a posterior gastro-enterostomy was performed, with excision of gland and portion of stomach wall for examination.

Pathologic Findings.—Extending from the middle of the greater curvature to the pylorus was an irregular mass involving the entire thickness of the stomach wall in such a way as to pucker the pyloric portion of the stomach, thereby causing stenosis of the pylorus. This mass was doughy in feel and the peritoneum covering it was edematous. There were numerous glands in the gastrocolic omentum, the greater omentum and about the greater curvature. No special changes were noted in the appearance of the liver.

Convalescence was straightforward with mixed treatment and neosalvarsan. The patient was discharged Feb. 25, 1915. Roentgen examination one month after operation showed that the gastro-enterostomy was working, but the deformity at the pyloric region of the stomach still persisted.

Pathologic Report.—Microscopic Examination: The gastric mucosa shows congestion, edema and dense cellular infiltration of the glandular structures. The glands themselves are much atrophied, especially in the deeper layers, where they are completely involved in the infiltration. Remnants of atrophic glands are found in the submucosa. Very little of the muscular coat is included in the material received at the laboratory. In the submucosa there is a very dense infiltration entirely replacing the normal structures, composed of flat endothelioid lymphocytes and diffuse tuberclelike masses. These tubercles contain large giant cells of the Langhans type. The tubercles are not quite so well defined as those seen in tuberculosis, and yet the structure is rather more rich in cells and giant cells than the ordinary gumma. The vascular lesions are not wholly characteristic of syphilis, but there is a certain amount of subendothelial proliferation, and in some places the vessels are obliterated by a growth of new endothelial cells. There is but little perivascular infiltration, especially in those areas outside of the specific lesion. Practically no necrosis is present in the lesion. Sections stained by the Levaditi method failed to show the *Spirochaeta pallida,* and no tubercle bacilli could be demonstrated. Sections from the lymph node show slight inflammatory reaction with moderate endothelial hyperplasia and distention of the lymph sinuses. The lesions in the mucosa and submucosa of the stomach are not characteristic of either syphilis or tuberculosis, but the absence of much necrosis and the diffuse nature of the infiltration, together with the vascular changes, point rather toward syphilis than toward tuberculosis. An absolute diagnosis, however, is not possible from the specimen received.

CASE 6.—*History.*—W. H., boy, aged 17, admitted to St. Luke's Hospital, Oct. 30, 1913, whose mother died of typhoid and father of arteriosclerosis, had been informed that he had inherited a certain disease from his father. For five years he had had discomfort in the region of the stomach. Eight months ago the pain became acute, but was intermittent in character, coming on two or three times a day without relation to eating. The patient had vomited at irregular intervals, but not persistently. He had no appetite, living principally on fluids. He was given four injections of salvarsan at the Rockefeller Institute beginning five weeks ago, followed by much improvement. He was able to eat more, but still suffered pain, which was attributed to a possible appendicitis. His general appearance was that of a poorly nourished boy, aged 17, but looking to be about 12. Pupils reacted sluggishly to light; teeth poor and slightly notched; cervical lymph nodes enlarged. Heart and lungs normal. Abdomen soft, normal to palpation. Knee jerks present. Weight 68 pounds. Height 5 feet ½ inch. Red blood cells 4,500,000. Hemoglobin 50 per cent.

Roentgen Examination.—This showed the stomach imperfectly filled out along the greater curvature (Fig. 4). The stomach was moderately dilated. There was a distinct residue at the sixth hour, and deformity of the pyloric third of the stomach which, with the previous findings and the history of positive Wassermann reaction, was sufficient to warrant a diagnosis of syphilis of the stomach. The patient continued on antisyphilitic treatment. He was discharged from the hospital, Nov. 7, 1913, and was referred back to the Rockefeller Institute, where he has been under continuous observation and treatment with the result that there has been a remarkable change in his condition.

Roentgen examination, March 2, 1914, showed that the deformity at the pyloric end of the stomach persisted. At the sixth hour there was a distinct residue in the stomach. March 18, 1914, the patient was again examined fluoroscopically and roentgenographically. This confirmed the findings of a deformity at the pyloric end of the stomach. There was less residue at the sixth hour than in the previous examination. March 14, 1915, Roentgen examination showed the pyloric end of the stomach still deformed, but at the sixth hour the stomach had emptied itself. At this time the weight had increased to 97 pounds; pain had disappeared and the patient was now able to eat and digest all sorts of food.

THE OPEN TREATMENT OF INFECTED WOUNDS

A PRELIMINARY REPORT

FREDERICK G. DYAS, M.D.
CHICAGO

The development of the surgical treatment of infected wounds has witnessed the use of a vast variety of substances and methods in the attempt to assist the healing powers of the individual. In the present aseptic era of surgery the treatment of an infected wound means in most cases the establishment of adequate drainage by various means and the application of voluminous dressings, either dry, sterile or moist antiseptic.

Pathology teaches us, and it is within the experience of every medical man, that the destruction of tissue caused by moist gangrene is far greater than that caused by dry gangrene. With this fundamental truth in mind I have endeavored to convert wounds, which in every way corresponded to moist gangrene, into areas of dry gangrene. Everyone is familiar with the crude methods employed by the Indians and other savage tribes for the preservation of carcasses of animals killed. These carcasses are placed high above the ground on the limbs of trees in order that the blood may drain from the muscles and that the tissue juices might be evaporated by the winds and sun. By this method meat may be preserved free from mold and putrefaction for a very long time.

It is a fundamental principle of bacteriology that heat and moisture are necessary for the growth and propagation of practically all pathogenic bacteria. Therefore, if it were possible to dry up the tissues and dehydrate the infected area, the invading organisms must be, if not entirely killed, at least greatly attenuated.

When an animal suffers a wound, usually in one of the extremities, it is a matter of common observation that the pus is licked from the suppurating area if it be within reach of the animal's tongue. No bandage is put around the affected area, which is exposed to the air and, in many cases, to the sunlight. As the result of this, one rarely sees the intensely infected wounds in the lower animals which one observes daily in a human being in the wards of a large general hospital. This is in harmony with the recent observations among the wounded on the battlefields of Europe. Infected wounds heal more rapidly under the influence of autogenous vaccines or serums, whether prepared scientifically or obtained by sucking the wound or chewing pus soaked bandages.

Furthermore, the treatment of all degrees of burns by the open air method is practically the uniform procedure in the hands of every experienced surgeon. By this method there is a rapid desiccation of the sloughing tissues and a drying up of the foul discharges. The absorption of toxic materials into the general circulation is very much diminished. The invading organisms which always infect the burned surfaces are markedly attenuated. The granulations are left free to grow and cover over the denuded area without being torn off daily with the dressings by entanglement of the protoplasmic elongations in the meshes of the gauze. Furthermore, the tissues are not macerated by the continuous local pus bath.

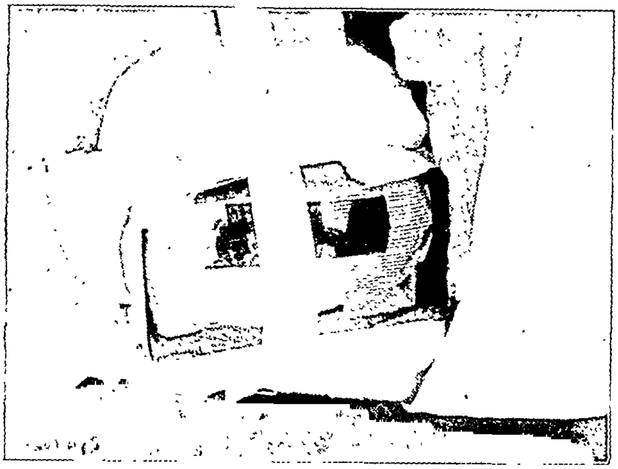

Fig. 1.—Infected appendectomy wound.

Rollièr has produced remarkable results in the treatment of surgical tuberculous affections which have gone to the worst stage by placing these patients with their lesions exposed to the air and sun. Most of these cases, naturally, were secondarily infected with pus organisms.

These results in the treatment of burns and surgical tuberculosis led me to undertake the treatment of old suppurating wounds by the open air method. This has been done now in several cases in Cook County Hospital with the most gratifying results. The patient is put to bed, if the affected area be on the lower extremity, as so frequently occurs in the form of foul varicose ulcers, a cradle is placed over the limb and thrown across this is a piece of mosquito netting to prevent contamination by flies or bits of dried tissue flying in the air. In some of these cases I have endeavored to hasten the healing process by playing the current of air from a small electric fan directly on the denuded surface for a period varying from fifteen minutes to half an hour four or five times daily. The rapidity with which the discharge diminishes and the odor disappears is nothing short of wonderful. The tissues on the old ulcer become rapidly dehydrated and in many cases become mummified, taking on the appearance and consistency of the bark of a tree.

At first the patients resent the fact that no dressings are put on the infected area, and complain that nothing is being done for them. After the lapse of two or three days, however, when they can see for themselves the rapid improvement which is going on, and can note the absence of the foul odor and the diminution in the discharge of pus, they express themselves as delighted at not having to undergo the painful dressings and the discomfort caused by pus soaked bandages.

In the process of desiccation, frequently large crusts or placques of inspissated serum, pus and epithelial and connective tissue elements are shed, leaving a clean and granulating surface which is devoid of pus. The surrounding tissues partake of the general improvement; the swelling and edema subside coincidently with the desiccation of the suppurating area.

Furthermore, this plan of treatment has the advantage of marked economy from the standpoint of dressings. The only attention which the wound requires on the part of the attending surgeon or intern is the occasional raising of crusts to allow the escape of pus or serum, or perhaps the occasional irrigation for a short time of some stubborn area. No dressings whatever are used. In some of our cases we have used, as in the treatment of burns, an inert desiccating powder which forms a cement-like substance with the desiccated tissues and serum.

The laity insist that bandages be put on wounds, and will naturally feel that the attending surgeon fails in fulfilling his whole duty unless he can make the patient who is suffering from a profuse, foul-smelling discharge acceptable in society. In other words, the treatment of these conditions is to be carried on in private. Under present day conditions it would, of course, be impossible for a patient with a putrefactive odor to expose a sloughing wound in public. Therefore, this treatment must always be confined to hospital or to home practice and no doubt this will in many cases prevent its use.

In ambulatory cases the wounds were protected by sterilized wire screening appropriately bent and the sharp points of the wire covered by strips of adhesive plaster.

The following histories are from the patients treated by me in Ward 10 in the Cook County Hospital:

REPORT OF CASES

Case 1.—Man, aged 51, a laborer, was admitted to the Cook County Hospital, March 8, 1915. Six years previously he was struck on the anterior surface of the right leg, receiving a wound which never healed, but slowly increased in size. He was able to continue working until six months prior to admission, when the ulcerated area was about as large as one's hand. At this time it began to increase more rapidly, and in spite of treatment the condition became constantly worse.

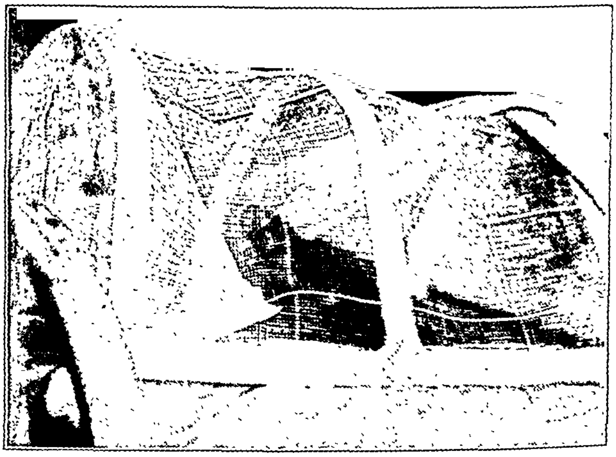

Fig. 2.—Infected wound of foot.

Past History.—Has had varicose veins of the right leg for ten years; has had rheumatism for seven or eight years. Denies syphilis; admits Neisserian infection seventeen years ago.

This man was put to bed and the treatment previously described given. Within five days, practically the whole ulcerated area had crusted over. The foul odor had entirely disappeared, as had also the edema and swelling. The crusts practically covered the entire denuded area and the patient was free from pain.

Case 2.—A laborer, male, was admitted to the County Hospital in November, 1914. He had had varicose ulcers of the left leg for three years. The patient was put to bed and the open air treatment instituted. Within two weeks the ulcerated area had almost healed and the patient left the hospital.

Case 3.—Man, a cook by occupation, was admitted to the County Hospital in September, 1914. He had varicose veins of both legs and a large, foul ulcer on the left leg. Open air treatment was immediately instituted, with the result that the ulcer healed within three weeks and the patient left the hospital apparently cured.

CONCLUSIONS

1. The advance made in the treatment of old suppurative wounds has not been in keeping with the advances made in other departments of surgery.
2. The treatment of suppurating areas by voluminous dressings, either sterile or antiseptic, macerates and devitalizes the tissues, fosters the development of the pathogenic flora and does not assist in the repair of the tissue.
3. It is always of advantage, when possible, to convert a moist into a dry type of gangrene. Therefore, the desiccating influence on the wound of the atmospheric air, in the absence of moist coverings of any sort, tends to attenuate infecting organisms.
4. The method is safe, economical and is in keeping with nature's own processes as observed in the lower animals.
5. The patient's period of convalescence is shortened and he absolutely suffers no pain.
6. In my experience, both in the treatment of wounds and of burns, the danger of contamination from the atmospheric air is negligible.
7. The addition of plenty of sunshine would be a valuable asset, but is not readily obtainable.

Coal Mine Fatalities in 1914.—According to a bulletin of the Bureau of Mines in 1914 there were 2,451 fatalities in the coal mines of the United States as compared with 2,785 in 1913, a decrease of 334. The principal decreases were in fatalities from coal dust explosions, 96 per cent., haulage 11 per cent. and falls of roof and pillar coal 10.6 per cent. The net decrease in underground fatalities was 365, or 14 per cent., a saving of one life for each day of the year. There were 331 fatalities from gas explosions, an increase of 240 over 1913. There were slight increases in fatalities from explosives, electricity and shaft accidents, but a net decrease for both underground and surface accidents of 12 per cent. The estimated total number of employees for the year was 742,868 as compared with 747,644 in 1913. The fatality rate was therefore 3.30 per thousand men employed in 1914 as against 3.73 in 1913. The amount of coal produced in 1914 is estimated to be 10.5 per cent. less than in 1913, but the fatality rate per one million tons of coal was 4.89 in 1913 and 4.81 in 1914. Improvement was due to many causes, not the least of which was said to be the cooperation of all concerned.

HYPERTROPHIES OF THE ENDOMETRIUM *

WILLIAM SISSON GARDNER, M.D.
Gynecologist to Mercy Hospital
BALTIMORE

In the study of the pathologic conditions of the endometrium which are not the results of infection, several are encountered that may be confused with each other or with the normal endometrium or with adenocarcinoma of the body of the uterus. The premenstrual endometrium is the normal form most frequently mistaken for some pathologic state; but occasionally a hypertrophic endometrium with narrow contracted glands, unless care is exercised, may be mistaken for a normal postmenstrual type. Among these noninflammatory hypertrophies are those associated with extra-uterine pregnancy, with ovarian growths and a third group for which we have at present no adequate explanation and which may be divided into two groups, the glandular and the interstitial.

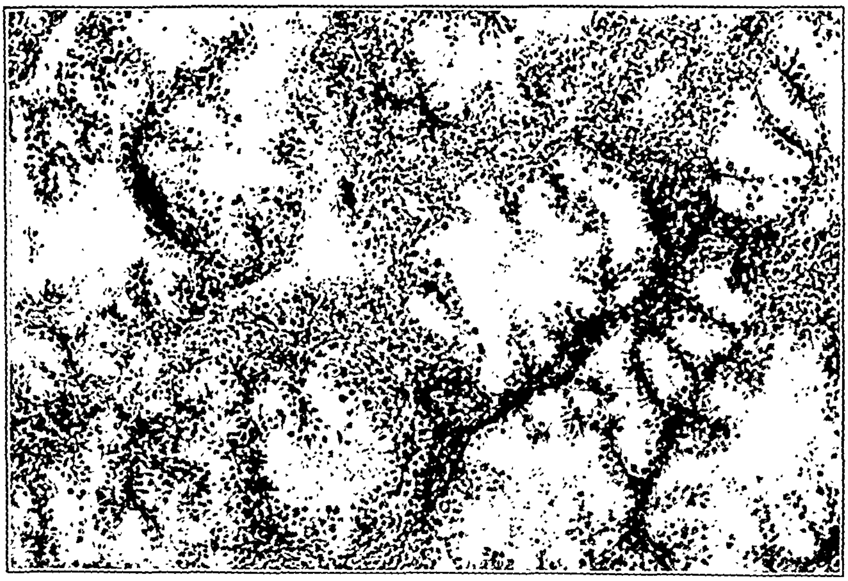

Fig. 1.—The endometrium of extra-uterine pregnancy. All the characteristics of the premenstrual type of endometrium are exaggerated.

On account of the frequent references that are made to endometritis and hypertrophy of the endometrium associated with uterine fibroids and retrodisplacements, I have included in this paper the results of my investigation of the endometrium as it is found in association with these two lesions.

Nonmalignant overgrowths of the endometrium are comparatively common. In some instances the whole endometrium is thickened; in others there are found pedunculated masses of greater or less extent. They occur most frequently between the ages of 40 and 50, but are also found at periods of life both earlier and later than this.

The symptom that attracts the attention of the patient is hemorrhage. This hemorrhage is a persistent but not a profuse flow in most cases, resembling in quantity a rather free menstrual period and continuing for weeks or months. In this it is not unlike the bleeding due to adenocarcinoma of the body of the uterus, and since the age incidence is the same, it is very important that we should have some definite means of distinguishing between them. The only reliable method is by the proper interpretation of microscopic examinations of uterine scrapings.

---

* Read at the Annual Meeting of the Medical and Chirurgical Faculty of Maryland, April 28, 1915.

EXTRA-UTERINE PREGNANCY

Figure 1 is the type found in extra-uterine pregnancy. Here we have every characteristic of the premenstrual endometrium magnified. The stroma cells are large and in appearance approach the decidual cells. The glands are very much dilated and very irregular in outline. The epithelium lining the glands is swollen and projects into the caliber of the glands, producing an exaggerated saw-toothed appearance.

This specimen was curetted from a woman of 24 who had bled excessively at each of the four last menstrual periods. The last flow ceased June 16, and she was curetted on the 28th, twelve days after the flow stopped. Under ordinary conditions one would expect to find an endometrium of the intermenstrual type. The history did not indicate an extra-uterine pregnancy, but the microscopic examination of an enlarged tube removed after curettement showed chorionic villi.

What appears to happen in extra-uterine pregnancy is the continuation of the same action on the endometrium that produces the premenstrual type; the continued action causing an exaggeration of the ordinary type. There is little doubt that these changes are due to the internal secretion of the ovary.

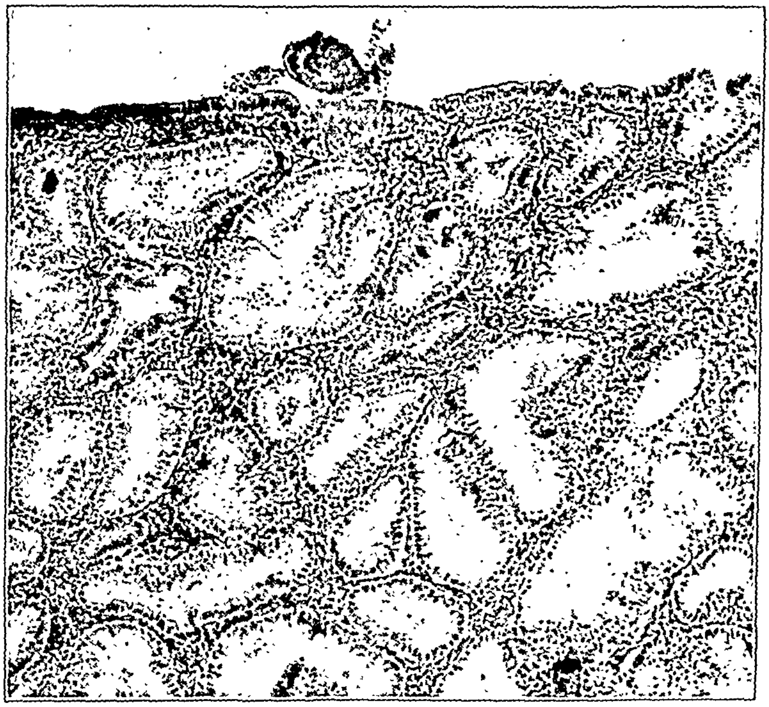

Fig. 2.—Ovarian type. Found when the uterine bleeding is due to an ovarian lesion. Glands dilated; stroma apparently diminished.

OVARIAN TYPE

Figure 2 is a type which has been found quite constantly in women who had been bleeding and where some marked ovarian lesion was present. This particular section was made from the scrapings of a young woman of 23 who had been bleeding constantly for several weeks. In one ovary there was a graafian follicle cyst and in the other a small multilocular cyst.

The section shows numerous dilated glands occupying the whole depth of the endometrium. Their outlines are fairly regular. In the lumen of the glands are some blood and much broken down epithelium. The epithelium lining the glands is in a single layer and somewhat enlarged, but does not buckle out into the caliber of the glands. The stroma cells are normal in size, but apparently decreased in number; that is, the volume of tissue between the glands is relatively small, and this makes the impression that there has been an actual atrophy of the stroma cells. In reality the increase in depth of the endometrium due to the dilatation of the glands distributes the stroma over a greater area than normal, and this gives the appearance of decrease in quantity. Both the epithelial cells and the stroma cells are deficient in chromatin. There is a slight increase in the small round cells.

The endometrium of this type resembles somewhat the normal premenstrual type, but is easily distinguished from it on superficial examination by the greater regularity of the outline of the glands and the apparent thinning out of the stroma. A closer examination shows that while the glands are dilated, the epithelial cells lining them are smaller and more regularly distributed than in the premenstrual type, and that the decrease in the stroma is only apparent and not actual.

GLANDULAR HYPERTROPHY

The true adenoma is shown in Figure 3. This illustration was taken from a case in which the growth projected through the cervix. The patient was 57 years of age and had been bleeding almost constantly for seven years.

This growth is characterized by the great increase in the number of glands associated with a moderate increase in the stroma. The glands are lined by a single layer of epithelial cells which have very large nuclei that contain much chromatin.

The uterine adenoma is very closely related to adenocarcinoma of the body of the uterus, and may be confused with it. The essential points of difference are that the epithelial cells in the glands of an adenoma are uniform throughout the growth, and present the same general appearance as in the normal uterine glands. And while the glands of a given specimen may vary some in caliber, the general appearance of all is the same. On the other hand, the epithelial cells lining the gland spaces of an adenocarcinoma are very irregular both in size and in chromatin content. Also the epithelium tends to pile up within the glands and later to break through into the stroma. No two of the gland spaces in an adenocarcinoma present the same kind of outline.

INTERSTITIAL HYPERTROPHY

Interstitial hypertrophy of the endometrium (Fig. 4) much more commonly involves the whole endometrium than does the glandular form. It is characterized by a great increase in the stroma and by very little if any increase in the number of glands. The glands may be so narrow as to resemble those of the postmenstrual endometrium, or they may be much dilated. What is most common is to find narrow and dilated glands irregularly distributed throughout the entire thickness of the endometrium. Without reference to the caliber of the glands, the epithelium lining them resembles that in the postmenstrual endometrium and retains its regularity of distribution. There is an entire absence of the saw-tooth appearance of the postmenstrual endometrium, as well as the piled up, irregular epithelium, that is so characteristic of adenocarcinoma.

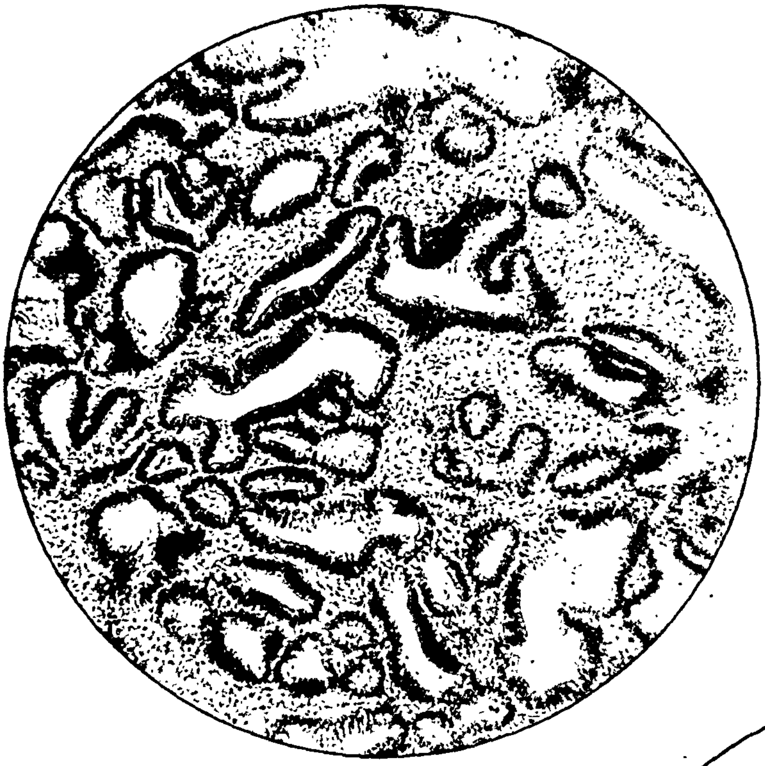

Fig. 3.—Glandular hypertrophy: adenoma. Great increase in the number of glands; epithelium of the glands regularly distributed.

This type of hypertrophy of the endometrium is not infrequently associated with marked hypertrophy of the uterine walls. In some instances the thickening of the uterine walls may be so great that on bimanual examination one may think that the enlargement is due to a submucous or interstitial fibroid; but on section the walls will be seen to be uniformly thickened, and the microscope shows that they are made up of normal cells.

THE ENDOMETRIUM WITH RETRODISPLACEMENT

The general appearance of the endometrium in retrodisplacement varies with the period of the menstrual cycle, but shows an almost constant increase above the normal of small round cells. The increase is in the scattered round cells and not in the defined groups. Of the endometriums examined, 50 per cent. were of the interval type and the other half were about equally divided between the premenstrual and postmenstrual types. Fifty per cent. of all slides showed marked congestion. In a few instances there was an increase of spindle cells. It is probable that these cells were the result of an old infection, but it was not always possible to decide this point.

The changes found in the endometrium of the retrodisplaced uterus are apparently the result of interference with circulation, due to the position of the uterus, and not caused by any active process. Before this was recognized, we followed the dictum that practically every retrodisplaced uterus had an infected endometrium which demanded curettage. Realizing several years ago the incorrectness of this teaching, we now curet very few patients on whom it is necessary to operate for retrodisplacements but rely on the correctness of the position of the uterus to relieve the symptoms of leukorrhea and menorrhagia due to the passive congestion of the endometrium.

THE ENDOMETRIUM WITH FIBROIDS

The endometrium associated with uterine fibroids acquires no characteristic appearance. All types are seen and none of them bear any direct relation to uterine hemorrhage. For example, of three cases in which the endometrium was of the senile type, one patient was menstruating normally each month, one was bleeding frequently and profusely, and one had lost no blood for five months. The variation in type is just what would

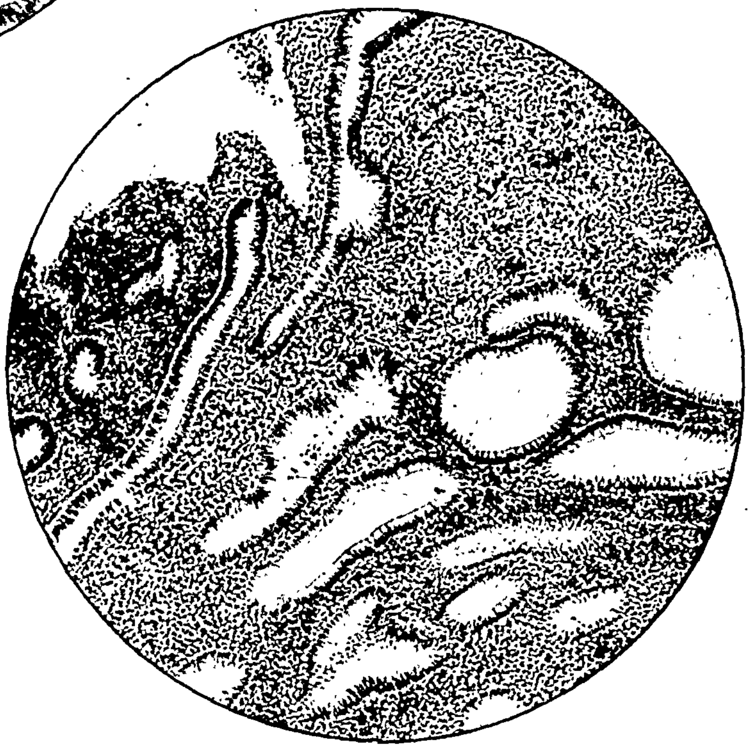

Fig. 4.—Interstitial hypertrophy. Stroma much increased in quantity; glands irregular in caliber and lined by low columnar epithelium.

be expected when we bear in mind that the hemorrhage caused by fibroids is due to a growth in the uterine wall and the consequent local disturbance of the circulation, and has no relation to the changes in the endometrium which result from ovarian influence.

6 West Preston Street.

PSEUDOMUCINOUS CYST OF THE APPENDIX

ITS RELATION TO PSEUDOMYXOMA PERITONEI [*]

D. B. PHEMISTER, M.D.
CHICAGO

Among the rarer lesions of the vermiform appendix, pseudomucinous cyst is of particular interest because of its peculiar pathologic nature, its mode of development, and the complications to which it sometimes gives rise. It results from the slow accumulation of an altered secretion of the appendix produced by a mild inflammatory process, and usually unaccompanied by subjective symptoms. There is a direct relation between the development of the disease and the normal involution of the appendix, as most of the cases have occurred between the ages of 35 and 50, or during the period in which retrogression with the obliteration of the appendix lumen takes place.

Very little was known about the normal secretion of the appendix before the recent experimental work of Heile,[1] which showed it to be of the same nature as the secretion of the cecum. It possesses both tryptic and amyloptic ferments which were demonstrated not only in the appendix secretion but also endocellularly in the mucosa of the organ. An internal secretion of hormones was also extracted from the wall of the human appendix which possessed the power of stimulating peristalsis of the intestines when injected into rabbits.

During an acute attack of appendicitis, the fluid which accumulates is an exudate varying in nature from serous to purulent or ichorous. The accumulation either disappears rapidly with the subsidence of the acute inflammation, or escapes into the surrounding peritoneal cavity through a perforation. Persistence of this type of fluid with chronic cyst formation is rare. However, cases are reported of stenosis of the proximal portion with pus accumulation in the part beyond leading to the formation of chronic empyema of the appendix, which never reaches a very great size, and possesses a much thickened wall similar to an empyema of the gallbladder. Chronic hydrops following milder attacks in which the appendix is filled with a simple serous exudate is also very rare, because the mucous membrane is preserved in such cases, and its secretion changes the character of the contents so that pseudomucinous cysts are nearly always the result.

There is much uncertainty as to the cause of the stenosis and retention of secretion. Normal involution of the appendix begins any time between the ages of 18 and 40, and on an average by the 39th year the mucous membrane and lymphatic tissue have disappeared at the expense of an increased submucous fibrous tissue, and the lumen of the appendix is obliterated. According to Sprengel, this obliteration of the lumen nearly always begins at the distal portion and progresses slowly toward the base. Faber examined longitudinal sections of appendixes undergoing involution, and reports that there are always signs of active inflammation with granulation tissue in the mucosa and submucosa about the point of obliteration. Sprengel also believes that involution of the appendix is usually accompanied by an inflammatory process; on the other hand, Ribbert and his followers assert that it is unaccompanied by inflammation. Possibly in some cases this process may begin at the proximal end of the appendix and thereby lead to retention and distention of the distal portion. Acute inflammation may destroy a part or all of the mucosa and lead to rapid obliteration of the lumen. It is probable that inflammation and involution are associated in varying degrees in the causation of the condition.

In many cases there is no history of preceding attacks of appendicitis, and in those with previous disturbance the attacks have been mild. Usually the lumen of the appendix is obliterated at the seat of constriction, but in some instances it is patent so that some of the gelatinous secretion may escape into the cecum. The amount of the appendix involved is variable. Usually it is almost the entire extent of the organ, the constriction being located close to the cecum; but it may be located anywhere along its course with dilatation of the part beyond. Rarely the lumen of both proximal and distal portions is obliterated and the middle portion dilated. In other instances the appendix remains little or undilated while one or more diverticula form along its course, which may reach considerable dimensions, as in the specimen reported by Dr. Herb,[2] now in the museum of Rush Medical College, in which the diverticulum measured 7 cm. in diameter. The changes in the wall of the dilated portion are variable. When moderately distended there is very little variation from the normal, except that the folds of the mucosa are obliterated. When the dilatation is more extensive, the wall becomes very thin and transparent in places, while in others there may be fibrous thickenings in the serosa. The mucous membrane is very much thinned and in places disappears. Along its surface may be seen secreting and broken down cells which appear to be giving rise to the peculiar contents of the lumen. The muscle fibers gradually atrophy and eventually are replaced by fibrous tissue. In very large specimens the wall consists of fibrous tissue which may be largely devoid of a mucous lining. The lumen is filled with a transparent gelatinous material which in some instances is thin, but usually is quite thick and escapes from the incised appendix either very slowly or not at all. It contains no feces, and in most instances in which bacteriologic examinations have been made, they have been negative. Chemically, the material gives the tests for *pseudomucin.* When acidulated with mineral acid and heated, a substance is precipitated which reduces copper salts; but no precipitation occurs on heating with acetic acid. Formerly some of these cases were mistaken for colloid carcinoma of the appendix, but histologic examination fails to reveal the presence of a tumor.

Clinically, the condition is remarkably free from symptoms It usually develops slowly without pain, but rarely following a mild attack of appendicitis. Occasionally there is a dull ache or light colicky pains in the appendix region. Sometimes the patient's attention is first attracted by the appearance of a mass in the right lower quadrant of the abdomen which on examination is smooth, oval or spherical, movable, and may extend beneath the brim of the pelvis. The condition is illustrated by the following case from the service of Dr. D. D. Lewis at the Presbyterian Hospital, to whom I am indebted for the privilege of making this report:

---

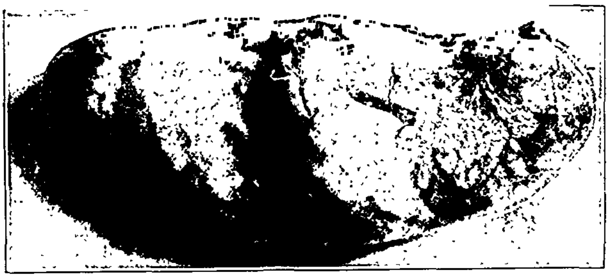
[*] From the Surgical Clinic of Rush Medical College.

[1] Heile: Beitr. z. klin. Chir., 1914, xciii, 520.

[2] Herb: Tr. Chicago Path. Soc., 1907.

V. N., woman, aged 36, married, with no history of previous abdominal disturbance, for a year had noticed a lump in the right lower quadrant of the abdomen which had gradually increased in size. It gave her no trouble until three months before, since which time there had been a dull ache in the region, but never any acute attacks of pain. Examination showed a visible and palpable elongated mass in the right lower quadrant, parallel to, and just above Poupart's ligament. It was movable and slightly tender and could be felt on vaginal examination. Under the diagnosis of an ovarian cyst, a median abdominal incision was made and a cystic tumor delivered from the right side of the pelvis. Its only attachment was found to be at the base of the cecum, and a mesenteriolum was present which served to identify it as a cyst of the appendix. The pedicle was clamped, the appendix cut away and the stump invaginated. The abdominal cavity was otherwise normal, there being no signs of peritoneal involvement.

The tumor (shown in the accompanying illustration) is a sausage-shaped mass 17 cm. long and 21 cm. in its greatest circumference. It is slightly curved along the border of the mesenteriolum, which extends about half its length. Blood vessels from the mesentery run out into the wall on either side and toward the tip. The surface of the appendix in most of its extent is smooth, but toward the end and in several places along its course there are slight bulgings of the wall, which in these regions is very thin and transparent. Between these slightly herniated portions, and particularly opposite the mesentery, there is considerable fibrous thickening of the wall, and some of the dense, opaque areas suggest calcified plaques. The appendix is filled with a thick, clear, gelatinous material which escapes very slowly from the excised windows of the hardened specimen. On chemical examination it proved to be pseudomucin, as it is not precipitated by the addition of acetic acid and does not coagulate on boiling but acquires a milky hue. Alcohol produces a coarse, thready precipitate. The appendix at the neck of the cyst is of normal size and structure except for some fibrous thickening of the serosa. The lumen is patent.



Appendix, with base ligated.

Microscopically the wall consists of fibrous tissue lined by an incomplete smooth mucous membrane, the regions where the wall protrudes being entirely devoid of a mucous covering. The cells of this layer are variable, the superficial ones being irregular and filled with mucus, which they seem to be liberating in the lumen by disintegration. In numerous places, but particularly where the wall is thickest, there is calcification of the submucous portion. All traces of muscularis have disappeared. *This is one of the largest specimens thus far reported.*

An attempt was made to produce the condition experimentally in dogs by obliterating the lumen of the proximal portion of the appendix. Seven animals were operated on in the following manner:

After removal of the contents of the appendix by stripping out, a longitudinal incision was made through the wall at its base, the mucosa dissected up and divided transversely, and each end closed with a purse-string suture. The incision in the muscularis and serosa was then closed, leaving the lumen obliterated for a distance of about 1 cm. In none of the cases were the blood vessels in the meso-appendix interfered with. Six of the animals died in from four to seven days, and at necropsy each showed a gangrenous appendix distended with an ichorous exudate similar to the gangrenous portion frequently seen beyond a fecal stone in human appendicitis. In four instances an extensive local and in two a general peritonitis was found.

One dog survived and was killed at the end of two months. At necropsy it was found that the operation had been unsuccessful, as a narrow lumen had reformed through the obliterated portion, and the appendix secretions escaped into the cecum without producing any dilatation.

Evidently the obstruction is produced too suddenly and accompanied by a too severe and extensive traumatism to bring about the condition of retention cyst formation, as gangrenous infection resulted in every case in which the lumen was successfully closed.

Complications of the disease are of interest. Rarely an acute inflammation of the cyst develops which may necessitate immediate surgical interference. A striking condition known as pseudomyxoma peritonei results from rupture of the cyst, with the escape of its contents into the peritoneum. This condition was first described by the gynecologist Werth as coming from the rupture of a colloid cystoma of the ovary; but subsequent observations showed that it may come from other organs, as the gallbladder and intestinal diverticula. Frankel, in 1901, described the first case arising from a perforated colloid cyst of the appendix. Since then about twenty cases arising from the appendix have been reported.

Perforation occurs usually without any accompanying symptoms, and the pseudomucinous material becomes disseminated over the peritoneal surface in various-sized masses. These may be confined to the vicinity of the appendix, but usually they are found in the pelvis and over the peritoneum of the lower part of the abdomen. The peritoneum may be irritated and throw out an investing fibrous sheath by which the particles become attached to it. The colloid material probably never contains living epithelial cells (as when derived from the ovaries) which proliferate and continue their secretion. The opening in the appendix usually persists so that there is a more or less constant escape of material into the abdominal cavity. In a few instances it has been found closed at operation or necropsy. These patients usually have little or no symptoms, as the contents are sterile. Loth recently reported a case in which rupture was accompanied by acute abdominal symptoms, and slight temperature and pain continued irregularly for four months, when the appendix was removed. Removal of the cystic appendix results in a cure, as the source of the material is removed and the remaining portion is silently absorbed. This peculiar complication was illustrated by a case in which Roberg[3] operated in 1907, the specimen of which is in the museum of Rush Medical College.

---

[3] Roberg, O. T.: Tr. Chicago Path. Soc., 1908, p. 180.

The patient was a woman aged 46. She came for advice because of a left inguinal hernia, the presence of a palpable tumor in the right lower quadrant not having been noted. At operation the peritoneum was studded everywhere with gelatinous masses, large numbers of which were removed from the hernial sac and from the culdesac of Douglas. The cystic appendix, which measured 13 cm. in length, was filled with a pseudomucinous material, and a small perforation existed through which the gelatinous contents escaped into the peritoneal cavity. The condition was at the time thought to be colloid carcinoma of the appendix, but following the operation all symptoms disappeared and one year ago the patient was living and well.

THE EXTERMINATION OF THE MOSQUITO

ALVAH H. DOTY, M.D.
NEW YORK

Those who undertake for the first time the work of mosquito extermination are confronted with various theories concerning the means by which this important protective measure may be successfully carried out, which are often perplexing. It is quite necessary that these theories should be promptly dealt with, in order that methods which have no practical value may be eliminated from the plan of procedure.

Included among these theories is the widespread belief that birds, fishes, bats, aquatic fowls, etc., render valuable aid in the extermination of the mosquito. Some years ago, it was seriously recommended that certain birds be propagated for this purpose, and more recently this has been suggested in connection with bats. The truth is that the number of mosquitoes devoured by birds and bats has no practical effect in diminishing the danger and annoyance caused by this insect. It is the presence of mosquitoes rather than the number involved which calls for action.

An attempt to propagate birds or bats for the purpose of exterminating the mosquito would be not only a foolish but also an unscientific procedure, and would end in disappointment. It may be pertinently asked, Who would attend to the propagation, care and distribution of these creatures in connection with this work, and what reason is there to believe that they would remain in sections where they are most needed? For neither one is dependent on the mosquito for sustenance. Besides, an enterprise such as this, assuming it could be reasonably carried out, would sooner or later cause a plague of birds and bats, and become an intolerable nuisance, particularly in the case of the latter, for there is no more unwelcome or repulsive visitor than the bat. Furthermore, the money spent in carrying out such an impracticable measure would go far toward defraying the expenses of destroying the breeding places of the mosquito.

This theory is about on a par with the belief that buzzards render valuable aid in cleaning streets and in the removal of garbage and other filth. To my personal knowledge, these birds were to a certain extent depended on for this purpose in Vera Cruz not many years ago, and until this medieval practice was abandoned, and modern sanitary measures enforced, Vera Cruz was the home of yellow fever.

The danger of these various impracticable theories concerning the extermination of the mosquito lies chiefly in the fact that they distract the attention of the public from the real means by which this work may be successfully accomplished.

There is also a popular theory that fish and aquatic fowls render valuable aid in the extermination of the mosquito by the consumption of the larvae found in bodies of water where they abound, and it is advocated that small fish be propagated for this purpose.

In order to understand more intelligently the impracticability of this theory, it is necessary to know something of the habits of mosquitoes, their breeding places, etc. For this reason, it may be said that in the United States, these insects are divided into two classes: the inland mosquito, of which the *Stegomyia* or yellow fever mosquito, and the *Anopheles* or malarial mosquito are types; and the *Sollicitans* or Atlantic Coast mosquito, commonly known as "striped legged" or "salt water swamp" mosquito.

The inland mosquito is the one most commonly dealt with, for it may be found in almost every state of the Union; whereas, the striped legged mosquito breeds on the salt marshes along the Atlantic Coast.

Some important and interesting facts have been obtained in recent years pertaining to the habits of these two groups of mosquitoes. In connection with my own work on Staten Island, conclusive evidence was presented, as a result of a careful and extended investigation, that a distinct line of demarcation exists between the breeding places of the inland and coast mosquito; that is, they do not, as it was formerly supposed, occur in the same places; for the striped legged breeds only on the salt marshes along the coast, while the inland mosquito never breeds in these localities, but in the interior. These results are in full accord with the experiences of the late Dr. John B. Smith, state entomologist of New Jersey, than whom no one has more carefully and exhaustively studied the habits of these insects, or has contributed more to their extermination.

This knowledge renders the work of mosquito extermination far easier; particularly along the Atlantic Coast; for if the striped legged mosquitoes are present, it may be depended on that their breeding places are not in the interior, but must be sought for in the salt water swamps. Yet this variety is often found inland, probably of its own volition; and in this way differs from the inland mosquito, which most likely prefers to remain close to its breeding place.

I suspect that the apparent migratory habit of the striped legged mosquitoes is due to the fact that they get beyond the confines of their breeding place and cannot find their way back, and continue their flight to obtain the food most suitable to them, which is probably the vegetation found in the salt water swamps. If this nourishment were obtainable everywhere I question whether they would go further from their homes than the inland variety. The fact that the striped legged mosquitoes have been found a number of miles at sea is satisfactorily accounted for by adverse winds.

Those who are not familiar with the vast area of swamp land along the Atlantic Coast can form no satisfactory idea of the enormous breeding places which these great stretches of land afford. The ground is always water soaked and spongy from the incoming tide, and surface water cannot escape by absorption. These swamps are sometimes traversed by natural ditches or creeks frequently containing very small fish, which regard as a choice morsel the larvae which find their way to these streams; but the number destroyed in this way is so infinitesimally small compared with the great and inexhaustible supply produced on these extensive breeding places, often miles in extent, that it offers no practical value in the extermination of mosquitoes of this variety; nor for various reasons would the propagation of small fish in these places, even if it could be reasonably carried out, make any practical difference in the result.

The inland mosquito will breed in almost any receptacle which contains water, preferably that which is stagnant and polluted; for the latter is rich in organic matter, and the larvae are voracious eaters. The fact that the inland mosquito breeds in unsuspected places, frequently not detected, is one reason why crusades against this insect are often unsuccessful.

Contrary to the general belief, mosquitoes, as a rule, do not breed in large bodies of water, but prefer small pools, where there is an abundance of vegetation and nourishment, and where they may be quiet. Mosquitoes are essentially vegetarians, notwithstanding the fact that the females, the only ones which bite, subsist largely on blood.

It is true that there are immense fresh water swamps found inland, particularly in the southern part of the United States, and these are most prolific breeding places; still these swamps, to a great extent, consist of comparatively small collections of surface water which are shallow and rich in vegetation. It may be added that while mosquitoes do not, as a rule, breed in large bodies of water, they lay their eggs along their borders, particularly if there is plenty of vegetation and the water is still.

While the *Anopheles* or malarial fever mosquito sometimes breeds in the same receptacle with other inland mosquitoes, the most common of which are the *Culex "pungens"* or *"pipiens,"* it is more often with its own kind. I have frequently found the anopheles' larvae in the open country in small collections of water covered with green scum, or having an abundance of vegetation and shade. These conditions are also found in the inland swamps already referred to.

The *Stegomyia,* or yellow fever mosquito, prefers to breed in built up communities, and in all sorts of receptacles which are favorable to insanitary conditions. During a visit to Havana some years ago, I was informed by a resident that he was unable to account for the presence of the *Stegomyia* in his house for a long time, but by continued and diligent search, found that the mosquitoes were breeding in small tin cans in which the legs of the refrigerator were placed as a protection against rats.

Mosquitoes have their likes and dislikes as to the selection of their breeding places. Just why they favor certain parts of the same section of the country for their propagation and avoid others is not fully known, but it is quite likely because of climatic conditions, or the character of breeding places and of the vegetation or nourishment which is available. That one place is more favorable than another cannot be doubted, for in some parts, mosquitoes appear regularly each year in great numbers, while in other localities, although these insects are annually present, they are few in number and do not constitute a great annoyance. The latter condition is often erroneously attributed to the presence of certain birds, etc.

A distinguished physician has stated that he was led to believe from personal observation that ducks are valuable agents in the extermination of the mosquito, and has suggested that in this way they might be of aid in the prevention of yellow fever and malaria.[1]

I am quite sure that the varied, innumerable and often unrecognized breeding places of the inland mosquito to which I have referred will quite clearly indicate that but little dependence can be placed on birds, fishes, fowls or animals, or anything else in the extermination of this insect, *except the destruction of its breeding place.*

The experimental stage in connection with the extermination of the mosquito has long since passed, and no doubt remains that this important work may be successfully accomplished, provided proper means are employed, and provided that the work is under the direction and control of federal, state or municipal authorities. The brilliant results obtained in Cuba, in Panama and on the Roman Campagna may be cited as conclusive proof that the inland mosquito may be exterminated; and the success of the work on Staten Island, where about ten square miles of salt water swamp land was drained and freed from breeding places, furnishes indisputable evidence that the striped legged mosquito may be dealt with in the same way.

The extermination of the mosquito can be accomplished only by the destruction of its breeding place. If birds, bats, fishes and fowls are of some aid in this direction, so much the better; but no dependence should be placed on these creatures in the work of elimination.

There is but one way by which the breeding place of the striped legged mosquito can be successfully destroyed, and that is by the proper draining of the swampland where these insects propagate.

The extermination of the inland mosquito requires a different procedure, for in this instance, small and innumerable receptacles of every description are to be dealt with, and these must be detected and destroyed. This will require the greatest amount of patience, but the reward will compensate for the time and trouble expended.

Furthermore, this work must be uniformly carried out in the entire infested section; for if the breeding places are destroyed only here and there, and adjoining ones are left untouched, successful results cannot be obtained, for there will be sufficient breeding places left to supply mosquitoes for all purposes. It is to secure uniformity of action in this direction that makes it so necessary that the work of mosquito extermination should be under some form of official control.

A word may be said regarding the use of petroleum oil. This agent should be employed only for temporary purposes, and must not be accepted as a substitute for the permanent destruction of breeding places. Semirefined and not the crude oil should be used, for the latter does not spread over the surface of the water, and the refined is rather too thin and is more expensive. Petroleum does not poison the larvae, but destroys them in a mechanical way; for when it is spread over the surface of the water as a film, it plugs up the minute openings of the respiratory tract of the larvae when they come to the surface for air, which is necessary every minute or so. The oil is afterward disposed of in various ways, and the receptacles after some days become breeding places again.

---

[1] Dixon, S. G.: The Duck as a Preventive Against Malaria and Yellow Fever, THE JOURNAL A. M. A., Oct. 3, 1914, p. 1203.

There is no agent which may be used as a substitute for petroleum oil, for it acts quickly and is cheap and not dangerous. The latter is an important consideration, for if poisonous solutions are used, for instance in pools in the country where animals have access, unpleasant results are apt to follow. Besides larvae are hardy little bodies, and not easily affected by poisonous agents. My experiments in this direction showed that larvae will remain alive for over twenty-four hours in a 1:1,500 solution of mercuric chlorid, and a comparatively strong solution of phenol (carbolic acid) and other products which are often advocated for this purpose.

While petroleum oil is a valuable temporary agent in dealing with the inland mosquito, it is worthless in the destruction of the striped legged or coast mosquito, chiefly on account of the great area involved, and must not be considered in connection with this work.

I may add that after long personal experience in the extermination of both the inland and coast mosquitoes, I have yet to know of any method by which this work may be successfully carried out except the destruction of breeding places. Besides, this is in full accord with the modern methods of preserving health; for it is the prevention of mosquitoes rather than their treatment that is called for.

205 West Fifty-Seventh Street.

FULLER'S EARTH; ITS ADSORPTIVE POWER, AND ITS ANTIDOTAL VALUE FOR ALKALOIDS *

BERNARD FANTUS, M.D.
Professor of Pharmacology and Therapeutics, College of Medicine, University of Illinois
CHICAGO

INTRODUCTION

For several decades fuller's earth (Parsons[1]) has been used extensively for the removal of coloring matter from oils. It owes this use to its capacity for adsorbing basic colors from solutions, which resides in the finest particles of the clay. The union between the basic substance and the earth is believed to be physical, as it can be easily broken up by use of proper solvents.

In 1910, John Uri Lloyd[2] of Cincinnati discovered that the addition of fuller's earth to alkaloids greatly diminished or almost abolished their bitter taste and that most alkaloids could be quantitatively removed from solutions by means of it. Further research revealed that this activity resided in the finest particles of the earth, which Lloyd separated by elutriation from the coarser portion and to which the name "Lloyd's reagent" has been applied.

In view of the theoretic interest as well as of the practical possibilities inherent in this property of fuller's earth, this research was undertaken to determine, first, the relation of alkaloids to "Lloyd's reagent" and to various other specimens of fuller's earths; and, secondly, to see to what extent the action of various alkaloids may be modified by combination with these earths. Lloyd, Eli Lilly & Co., and various producers of fuller's earth have kindly supplied liberal quantities of material, by means of which the following data were obtained.

TABLE 1.—ADSORPTIVE VALUE AND ACIDITY OF VARIOUS SPECIMENS OF FULLER'S EARTH *

Specimen	Morphin Sulphate, 0.5% sol.	Quinin Bisulphate, 0.5% sol.	Malachite Green 1%, with 0.25% Morphin	For 100 Gm. Earth Phenolphthalein, c.c. of Tenth Normal Sodium Hydroxid	Congo-red
Colloidal portion of Lester Clay without drying.†	6.5	9	20	77	Purplish.
Lloyd's Reagent, Eli Lilly & Co.	8	10	30	155	Bluish purple.
General Reduction Co., Dry Branch, Ga.	20	30	60	175	Blue.
Olson Fuller's Earth, Benton, Ark.	26	44	70	20	Red with trace of blue.
Specimen F (source unknown)	28	50	75	215	Bluish purple.
Lester Clay Co. (xx F) Jacksonville, Fla.	36	50	100	25	Reddish purple.
Specimen D (source *unknown*)	52	74	105	30	Red with trace of blue.
Midway, Fla., Fuller's Earth	70	80	120	40	Bluish red.
Manatee (E x F) Ellenton, Fla.	80	104	115	15	Bluish red.
Atlantic Refining Co. (xxF) Ellenton, Fla.	110	140	130	5	Red with faint tr. of blue.
Specimen E (source unknown)	200	280	160	5	Red with faint tr. of blue.
Pear's Precipitated....	500	400	600	5	Red with faint tr. of blue.
Kaolin	600	600	1,000	0	Red.

* The figures in the first three columns indicate parts by weight of the respective earths required to remove from solution 1 part of the substance named at the head of the column. The figures in the fourth column indicate c.c. of tenth normal sodium hydroxid needed to neutralize 100 gm. of fuller's earth, phenolphthalein being used as indicator. *The specimens are arranged in order of adsorptive power.* Variations in adsorptive power of different specimens from the same source have been noted.

† Drying would reduce activity somewhat.

THE ALKALOID ADSORBING QUALITY OF VARIOUS SPECIMENS OF FULLER'S EARTH

This was studied by briefly shaking accurately measured quantities of alkaloidal solutions with varying amounts of fuller's earth, filtering and then testing the filtrate for the alkaloid to determine the smallest amount necessary to remove the alkaloid from the solution. The figures given in Tables 1 and 2 show how many parts of fuller's earth had to be used to remove 1 part of alkaloid from solution. There is some difficulty in deciding on the end-point in these determinations, owing to the fact that water dissociates the combination to a slight extent, so that it is almost impossible to get rid of traces of the alkaloids in the filtrate. Therefore the smallest amount of fuller's earth that would remove the alkaloid as thoroughly as a larger amount was the quantity looked for.

In Table 1, the various earths have been arranged in order of their adsorptive power. It must be understood that the figures given in this table are only of relative value. Slight modifications in the technic of the test give quite different results. Nevertheless, when the same technic was applied to each of the different specimens, their relative position in the table was well maintained. It must furthermore be realized that the adsorptive power of fuller's earth from various sources depends, to a certain extent, on the degree and uniformity of fineness of the specimen. Mere sifting raises the value, if a considerable amount of coarse particles be present; so does elutriation. Nevertheless there is a limit to which the adsorptivity of any one specimen may be raised by these means.

---

* From the Pharmacologic Laboratory of the College of Medicine of the University of Illinois.

[1] Parsons, Charles L.: Fuller's Earth, Bull. 71, Mineral Technology, Dept. of the Interior, Bureau of Mines, October, 1913.

[2] Lloyd, John Uri: Lloyd's Reagent—Preliminary Announcement, Jour. Am. Pharm. Assn., May, 1914, iii, No. 5, p. 625.

It will be noted that "Lloyd's reagent" is considerably more powerful than any one of the specimens of fuller's earth. It will also be seen that the specimens obtained from Ellenton, Fla., are quite deficient in this power. Pear's precipitated fuller's earth, a very fine white powder, is surprisingly inert. The activity of kaolin is practically nil. In view of the fact that the United States Dispensatory as well as the National Dispensatory quote "fuller's earth" as one of the synonyms of kaolin, it seems of importance to point out that there is a marked difference in the adsorptive power of these substances.

Kaolin as well as fuller's earth is considered to be essentially composed of hydrous aluminum silicate; the latter being merely less pure than the former. That this is the case can be readily seen by comparing the composition of kaolin (Watts[3]) with that of fuller's earth (Vaughan[4]) and of Lloyd's reagent (Waldbott[5]).

	SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO	Alkalies	Water
Kaolin	45.40	37.34	1.92	0.44	0.20	0.52	14.0
Fuller's Earth..	57.26	18.33	1.87	2.58	1.06		18.4
Lloyd's Reagent	55.30	9.82	14.80	1.58			17.41

It is an interesting question, why such great difference in adsorptive power exists among these substances. The following theories present themselves: First, it might be due to a physical difference, namely, the amount of colloidal material present; secondly, it might be due to difference in reaction; thirdly, it might be due to difference in chemical composition.

THE AMOUNT OF COLLOID IN FULLER'S EARTH

Ashley[6] believes that the power of adsorbing certain dyes by clay supplies a measure of the amount of colloid present. He selected malachite green as the best dye known for this purpose, as it is wholly noncolloidal. Colloidal dyes, even if as feebly colloidal as methylene blue, introduce complicating factors that vitiate results, as may be seen by comparing the figures for malachite green with those arrived at with methylene blue: of Specimen F 40 times the amount was required, of Specimen D 60 times, of Specimen E 50 times, of Midway, Fla., fuller's earth 60 times—figures that are very near together in spite of great difference in alkaloid adsorbing power of these various specimens. Ashley agitates the clay with the dye solution for an hour, by means of a small ball mill, permits the clay to settle over night, and determines the amount of malachite green adsorbed by comparison with dilutions of a standard solution of malachite green. He found that half an hour's settling gave results that were too erratic, in view of the slow sedimentation of some specimens of fuller's earth. It must be understood that colored colloidal material in suspension makes the solution appear darker, so that it would seem less color was adsorbed, leading to the judgment that the clay is less colloidal, when it would be actually more colloidal than another clay that settled readily. I believe I have hit on a much less troublesome, more rapid and probably as accurate method of estimating the adsorptive power of fuller's earth by means of malachite green. The addition of a small quantity of an alkaloid, for example, morphin, to a fuller's earth suspension produces immediate deflocculation. On the other hand morphin does not readily salt out the malachite green. I therefore used in the determination of the malachite green figures (Tables 1 and 2) a solution of the following composition:

Malachite green	1.0
Morphin sulphate	2.5
Distilled water to................................	1,000

Filter after prolonged agitation.

The amount of fuller's earth needed to remove a certain quantity of malachite green from this solution, expressed in multiples of that quantity, is represented by the figures in Table 1. It will be noted that these figures run quite closely parallel to the figures indicating alkaloid adsorptive power. Other electrolytes, for example, sodium chlorid, also produce deflocculation of suspended fuller's earth. However, considerably larger quantities of sodium chlorid are needed to produce this result promptly: quantities that are capable of salting out the malachite green, thus interfering with the test.

From Tables 1 and 2 it will be seen that the adsorption of malachite green runs parallel with the adsorption of alkaloids, and is therefore presumably due to the same cause. To use this adsorption as a measure of the amount of colloid present, as is proposed by Ashley, merely rests on the assumption that it is due to colloid. It does not prove that this is the case. Inasmuch as other colloids experimented with, such as colloidal aluminium hydroxid, colloidal ferric hydroxid, colloidal silicic acid, mastic emulsion, do not have the power of adsorbing alkaloids to nearly the same degree as active fuller's earth, it is reasonable to assume that we have here a case of specific adsorption; and that, while no doubt the colloidal state is necessary for this effect, it is not the essential cause of it.

THE "ACIDITY" OF FULLER'S EARTH

To determine whether the acid reaction generally displayed by fuller's earth is the cause of the effects observed, the degree of "acidity," or rather the power of the earth to adsorb bases, was determined for each specimen by titration of 2 gm. of the earth, suspended in 100 c.c. of distilled water, with tenth normal sodium hydroxid, using phenolphthalein as an indicator. A priori one might expect that the power of adsorbing alkali would be proportionate to, or at least run parallel with, the power of adsorbing alkaloids. This, however, is not the case, as can be seen by a glance at Table 1. Nevertheless, specimens devoid or practically devoid of acidity, like kaolin or Pear's precipitated fuller's earth, fail to adsorb alkaloids and those of lowest acidity are lowest in the list of alkaloidal adsorbents. Hence the presence of "acidity" is necessary to enable fuller's earth to adsorb alkaloids; though its degree is by no means a measure of the degree of this power. It therefore appears there are at least two factors involved in the adsorption phenomenon under consideration: the one the "acidity," the other the colloidal state. Whether the reason for the comparatively high adsorptive power of "Olson" and "Lester" fuller's earth, in spite of their rather low "acidity," is due to a relatively higher content of colloid than is present in more acid earths of lower activity, or whether there are two different "acidities" involved, one of importance in adsorption of alkaloids and the other not, remains to be settled. Nor have I the data at hand, at present, to discuss with any degree of profit the other theory previously advanced. On work on these questions I hope to report in the near future.

TABLE 2.—PROPORTION OF FULLER'S EARTHS NEEDED TO REMOVE 1 PART OF ALKALOIDAL SALT FROM SOLUTION

Alkaloidal Salt	Lloyd's Reagent	General Reduction Co.	Olson Fuller's Earth	Lester Fuller's Earth
Morphin sulphate..........	8	20	26	36
Quinin bisulphate..........	10	30	44	50
Nicotin hydrochlorid.......	20	50	100	110
Cocain hydrochlorid........	20	75	95	150
Aconitin nitrate............	50	70	100	120
Strychnin sulphate.........	40	110	120	200
Colchicin hydrochlorid.....	130	160	200	
Malachite green............	30	65	70	100

The addition of Congo-red to fuller's earths enables one to determine roughly, but quickly, the presence and the degree of "acidity." It will be seen (Table 1) that all the earths that gave a blue or purple color with Congo-red were found active, while with the inactive kaolin there was no change; the others produced intermediate tints.

THE ADSORPTION OF VARIOUS ALKALOIDS BY FULLER'S EARTH

It will be seen from Table 2 that the various alkaloids differ in their relation to fuller's earth. For instance, a smaller quantity of an earth is needed to remove a morphin than a quinin salt; and less fuller's earth is needed to remove quinin bisulphate than strychnin sulphate. Colchicin needs the largest amount. As will presently be seen, these relations are significant in connection with the antidotal value of fuller's earth for these different alkaloids.

THE ACTIVITY OF ALKALOIDAL FULLER'S EARTH COMPOUNDS

The alkaloidal fuller's earth compounds resist dilute acid; but are decomposed by alkalies, even as dilute as fiftieth normal sodium carbonate, which is approximately the alkalinity of the intestinal juice. When fuller's earth compounds of various alkaloids are treated with fiftieth normal sodium carbonate solution and the solution is acidified, it yields precipitates with Mayer's reagent, apparently in proportion to the solubility of the free alkaloid in water: the nicotin precipitate is much more copious than that obtained with cocain; and the latter more abundant than the aconitin or the strychnin precipitate. Emetin yields only a trace. The concentration of the morphin solution obtained under these circumstances is below the threshold of distinct precipitation by Mayer's reagent, as is also a saturated solution of morphin in water; it yields, however, a copious precipitate with phosphomolybdic acid. Colchicin does not, of course, precipitate with Mayer's reagent, but does with tannic acid.

In view of this dissociability of the alkaloidal fuller's earth compounds by very dilute alkali, it is easy to understand why they become active in the animal body in spite of the fact, as Gordin and Kaplan[7] have shown, that the digestive ferments have no disrupting effect on these compounds. Being insoluble in acid liquids, even in the presence of pepsin, they pass through the stomach without acting on this viscus and without being acted on. On arriving in the intestine, they are gradually dissociated into their constituents, yielding the alkaloid to absorption. This explains why the general action of alkaloids, administered in this combination, is markedly delayed; and why a larger dose is needed to obtain the same effect.

TABLE 3.—EFFECT ON RABBITS OF SMALL FATAL DOSE OF STRYCHNIN SULPHATE, 5 MG. PER KILOGRAM GIVEN ORALLY, WITH AND WITHOUT FULLER'S EARTH AND ACID

Rabbit		Dose			Effect

D1 2	1,870	0.0187	5.60*	5.60 NaH_2PO_4*	Convulsions in 15 min.	Death in 17 min.

* Five minutes later.

This modification of the action of alkaloids is of toxicologic, of pharmacodynamic, and of therapeutic interest. The diminution of taste, for instance, obtained in this manner has made it possible to produce perfectly pleasant sweet tablets of strychnin (Fantus[8]) for administration to children. The absence of effect on the stomach might be of value in connection with some of the alkaloids. Though, in case of ipecac, the removal of the emetic action by means of fuller's earth also seems to destroy action on certain infusoria, as I have found in as yet unpublished experiments. The delayed absorption might increase the effect on the intestine and its contents; for example, the quinin combination might exhibit amebicidal action in the intestine. The delayed absorption of cocain may make the cocain combination of value as an antipruritic in weeping skin disease. Work on some of these questions is being carried on at present.

THE NAMING OF THE ALKALOIDAL FULLER'S EARTH COMPOUNDS

Inasmuch as some of these alkaloidal fuller's earth compounds are likely to prove of therapeutic value, it might be well to discuss the terms that have been applied to them. Lloyd named these "alcresta" alkaloids. It is under this title that Eli Lilly & Co. propose to place them on the market. The name is unfortunately not descriptive of the nature of the compound.

McGuigan[9] has applied the name "colloidal" strychnin to the strychnin compound with fuller's earth; a name I believe to be erroneous, as the moment the combination between the colloid and the alkaloid occurs, the colloidal state is destroyed and a coarse suspension results, as may be shown by the readiness with which morphin produces deflocculation of a fuller's earth sol or gel. It appears to me that the best name to apply to the strychnin compound would be "strychninated fuller's earth"; to the morphin compound "morphinated fuller's earth"; to the cocain compound "cocainated fuller's earth," etc.; terms analogous to "chlorinated lime" and "sulphurated potash."

Lloyd at first hoped that his reagent would prove a universal antidote for alkaloids and he describes it as one of the bitterest disappointments of his life when it was shown by Dr. Felter, in 1911, that the combination of Lloyd's reagent with strychnin was still capable of killing a dog in convulsions. Lloyd suggested to me that the addition of tartaric acid or of stearic acid to his reagent might raise its antidotal value. It will presently be seen that this is indeed the case with tartaric acid. Experiments with the stearic acid combination proved negative.

The experiments recorded below were undertaken primarily to study the toxic action of alkaloidated fuller's earth. It soon became apparent, however, that fuller's earth did possess antidotal value against certain alkaloids, while it had little value against others, as will be shown by the following data.

TABLE 5.—EFFECT ON DOGS OF FATAL DOSE OF STRYCHNIN SULPHATE, 2 MG. PER KILOGRAM, GIVEN ORALLY, WITH AND WITHOUT FULLER'S EARTH AND ACID

ANTIDOTAL VALUE IN STRYCHNIN POISONING

The antidotal value of fuller's earth in strychnin poisoning in the rabbit may be estimated from Tables 3 and 4. It will be seen in Table 3 that 5 mg. per kilogram is invariably convulsive and frequently fatal for small rabbits; that, on the other hand, a large rabbit (A 4) showed no effect from such a dose. Eliminating, therefore, the only other large rabbit in this series (D 5) from consideration, we find that fuller's earth alone is not antidotal to strychnin. The addition of tartaric acid or of sodium dihydrogen phosphate to the fuller's earth renders it, however, capable of preventing convulsions and of saving life in small rabbits, even if administered five minutes after the poison has been given. The sodium dihydrogen phosphate showed itself superior to the tartaric acid by having this effect invariably, while with the tartaric acid combination convulsions and deaths have occurred. The dose of 10 mg. per kilogram (Table 4) is invariably fatal; and yet the addition of tartaric acid or of sodium dihydrogen phosphate to fuller's earth has enabled it to prevent effects, if administered at the same time; but not, if administered five minutes later. Against 15 mg. per kilogram, fuller's earth with sodium dihydrogen phosphate has been useless so far as saving life of rabbits is concerned; but it, no doubt, postponed the effects to a considerable degree, as will be seen from the following observations:

---

[9] McGuigan, Hugh: A Colloidal Compound of Strychnin and Its Pharmacology, The Journal A. M. A., Nov. 28, 1914, p. 1933.

Rabbit D 10, weighing 907 gm. was given 0.015 gm. strychnin with 4.50 gm. each of fuller's earth and of sodium dihydrogen phosphate. Death occurred in four hours and thirty minutes.

Rabbit D 11, weighing 2,660 gm. was given 0.040 gm. of strychnin with 13.3 gm. each of fuller's earth and sodium dihydrogen phosphate. Death occurred in thirty-two hours.

Table 5 shows that a dose of 2 mg. per kilogram is invariably fatal to dogs. The addition of fuller's earth saved life, but did not prevent convulsions. The addition of tartaric acid and of sodium dihydrogen phosphate frequently prevented convulsions and generally saved life. However, emesis was so frequently produced as to vitiate the results. Therefore morphin was given about one hour before the administration of the poison. This preliminary administration of morphin, of course, produced vomiting and often defecation within the hour, followed by a depression of the vomiting center, so that the doses were now regularly retained. Experiments A 3 to A 6 (Table 5) show that the morphin does not save the life of the animal, though it delays results. Experiments D 3 to D 6 show that fuller's earth and sodium dihydrogen phosphate are capable of saving life, even though no emesis takes place. The fact that it was possible to save the life of morphinized dogs, even if the antidote was given five, ten and fifteen minutes after the poison, while the antidote failed to produce such result without the morphin, is most interesting and requires further study. Possibly it is due to delayed evacuation of the stomach.

TABLE 6.—EFFECT ON RABBITS OF FATAL DOSES OF MORPHIN GIVEN ORALLY WITH AND WITHOUT FULLER'S EARTH

Rabbit		Dose			Effects	
No.	Weight, Gm.	Morphin Sulph. per Kg.	Accom. (+) or followed	Fuller's Earth	Symptoms	Result
A 1	850	1 mg.	....	0	Depr. Conv. in 2 hrs.	Death in 3 hrs.
B 1	794	1 mg.	+	20.00	Some depression......	Recovery.
B 2	1,248	1.6 mg.	+	50.00	Some depression......	Recovery.
B 3	1,134	2 mg.	+	56.25	Some depression......	Recovery.
B1 1	510	1 mg.	10 min. later	12.50	Some depression......	Recovery.
B1 2	624	1 mg.	15 min. later	15.75	Some depression......	Recovery.
B1 3	1,134	1 mg.	20 min. later	30.00	Depr. Conv. in 30 min.	Death in 2 hrs.
B1 4	740	1 mg.	20 min. later	18.50	Depr. Conv. in 2 hrs...	Death in 3 hrs.

A dose as large as 4 mg. per kilogram makes demands on the antidote that it is not able to meet, as will be seen from the following experiments:

Dog C 6, weighing 9 kg., was given, at 9:15 a. m., 0.036 gm. strychnin with 5.4 gm. each of fuller's earth and tartaric acid. It was found dead next morning, no convulsions having been observed.

Dog C 7, weighing 13.5 kg. was given at 9:30 a. m. 0.108 gm. strychnin with 9.1 gm. each of fuller's earth and of tartaric acid. There was slight emesis at 11 a. m. The animal was found dead next morning, no convulsions having been observed.

ANTIDOTAL VALUE IN MORPHIN POISONING

Table 6 shows that the antidotal value of fuller's earth is much greater for morphin than it is for strychnin. This is probably due to the fact, shown in Tables 1 and 2, that morphin is much more readily removed from solutions by fuller's earth than are any of the other alkaloids, as well as to the slight solubility of the alkaloid morphin and the large dose needed to produce death in these animals. It will be noted that the mere addition of fuller's earth saved rabbits from as much as twice the fatal dose of morphin, and that fuller's earth was still capable of saving life, if given ten and fifteen minutes later; but not if given twenty minutes later. The administration, at intervals, of fuller's earth in morphin poisoning in human beings, even after hypodermic administration of the poison or evacuation of the stomach, appears indicated; as the morphin excreted into the stomach would be adsorbed by the clay and its reabsorption prevented or at least delayed.

TABLE 7.—EFFECT ON DOGS OF FATAL DOSES OF COCAIN WITH AND WITHOUT MORPHIN AND FULLER'S EARTH

Dog		1 Hour Prev. Hypo. of Morphin, 5 Mg. per Kg.	Dose		Effects	
No.	Weight, Gm.		Cocain, Gm.	Fuller's Earth	Symptoms	Result
A 1	7,250	0	0.1 per kg.	0	Convulsions in 25 min.	Death in 90 min.
A 2	3,000	0	0.1 per kg.	0	Convulsions in 15 min.	Death in 20 hrs.
A 3	3,800	0	0.2 per kg.	0	Convulsions in 7 min.	Death in 16 min.
A 4	7,500	0.040	0.1 per kg.	0	Whining occ.	Recovery.
A 5	5,946	0.025	0.1 per kg.	0	Depr., later excit.	Recovery.
A 6	6,850	0.035	0.2 per kg.	0	Convulsions in 220 min.	Death in 260 min.
A 7	7,140	0.035	0.2 per kg.	0	Convulsions in 15 min.	Death in 30 min.
A 8	4,700	0.030	0.2 per kg.	0	Depression..............	Death in 20 hrs.
B 1	6,000	0	0.1 per kg.	60.0	Emesis in 85 min.	Recovery.
B 2	12,000	0.600	0.1 per kg.	120.0	0	Recovery.
B 3	6,800	0.035	0.2 per kg.	136.0	0	Recovery.
B 4	4,800	0.025	0.2 per kg.	96.0	0	Recovery.
B 5	3,740	0.020	0.2 per kg.	76.0	0	Recovery.

ANTIDOTAL VALUE IN COCAIN POISONING

In view of the local anesthetic quality of cocain, it is of interest to note that the dog B 1 (Table 7), that received it together with fuller's earth, vomited. Evidently the compound produced by fuller's earth with cocain is not decomposed in the stomach, which is entirely in accord with the general tendency of the alkaloidal fuller's earth compounds not to give up the alkaloid to an acid solution. This made it necessary again to use hypodermic injections of morphin, one hour previously, to prevent the emesis. However, inasmuch as morphin is an antagonist to cocain, as will be seen by comparing the result in A 1 and A 2 with A 4 and A 5, it was necessary to use a large fatal dose of cocain (0.2 gm. per kg.), in order to have a fatal dose in the presence of morphin. The antidotal value of fuller's earth under these circumstances is demonstrated by the uniformly fatal results in experiments A 6, A 7 and A 8, as compared with the uniformly negative results in Experiments B 3, B 4 and B 5. Evidently fuller's earth is an antidote to cocain, and it does not need acid to produce this effect, at least in the presence of morphin, which probably enhances the antidotal effect of fuller's earth by delaying the emptying of the stomach.

ANTIDOTAL VALUE IN NICOTIN POISONING

Rabbits are killed within twenty minutes by 0.20 gm. nicotin per kilogram, as will be seen from Table 8. The addition of fuller's earth to such a dose is followed by recovery. A dose of 0.40 gm. per kilogram is fatal even when fuller's earth and sodium dihydrogen phosphate are added. If the antidote is given five minutes after the poison was administered, it is unable to save life. Evidently nicotin acts too rapidly to admit of any interval between the giving of the poison and of the antidote.

TABLE 8.—EFFECT ON RABBITS OF FATAL DOSES OF NICOTIN, GIVEN ORALLY WITH AND WITHOUT FULLER'S EARTH AND ACID

Rabbit		Dose				Effects	
No.	Weight, Gm.	Nicotin per Kg.	Accom. (+) or Foll.	Fuller's Earth	Acid	Symptoms	Result
A 1	1,500	0.10	......	0	0	0	Recovery.
A 2	964	0.20	......	0	0	Convulsions in 15 min.	Death in 20 min.
A 3	900	0.20	......	0	0	Convulsions in 12 min.	Death in 20 min.

D 2	680	0.40	+	13.6	6.8 NaH_2PO_4	?	Death within 20 hrs.

ANTIDOTAL VALUE IN IPECAC POISONING

Emetic Dose.—If two dogs of similar size and with empty stomachs are chosen, and one of these is given, by means of the stomach tube, 0.3 c.c. per kilogram of fluidextract of ipecac mixed with ten times the volume of water, while the other receives the same dose with the addition of 3 gm. of active fuller's earth per cubic centimeter of fluidextract used, the first dog will vomit profusely and many times—usually not until after half an hour, but within one hour—and soon afterward may have bowel evacuations, which sometimes become bloody. The other dog will show no effects whatever excepting perhaps, occasionally, a looseness of the bowels on the next day.

Fatal Dose.—A dose of 1.5 c.c. of fluidextract of ipecac per kilogram has been found uniformly fatal in dogs, as will be seen from the following experiments:

Dog A, weighing 15.5 kg. was given 23.25 c.c. of fluidextract of ipecac, diluted with 232.5 c.c. of water, at 9:42 a. m. Formed bowel movement occurred at 11:25; vomiting at 12, and again at 12:15; semiliquid bowel movement at 12:30. Several other attacks of emesis occurred during the afternoon, the animal refusing food, but drinking water freely. The next day it was found that the animal had bloody bowel movements; and on this day it died at 10 a. m. Necropsy showed hemorrhagic gastro-enteritis. The urine obtained from the bladder contained albumin and a few red blood corpuscles, but no casts.

Similar results were obtained in three other dogs. A different result was obtained in Dog E. This dog, weighing 7.25 kg. was given 10 c.c. of fluidextract of ipecac diluted with 100 c.c. of water. Within half an hour, the dog showed marked depression, salivation, and had a fluid defecation, but did not vomit. The animal died within five hours after the administration of the poison, without having had emesis or bloody purging. On post-mortem examination, performed twenty hours later, the gastro-intestinal tract was found pale and without gross evidence of inflammation. Death had evidently occurred too soon for inflammation to have developed.

Entirely different is the result when the fatal dose of fluidextract of ipecac is mixed with fuller's earth, 3 gm. per cubic centimeter, as may be seen from the protocol of experiment on Dog J. This animal, weighing 9.5 kg., was given 14.25 c.c. of fluidextract of ipecac diluted with 142.5 c.c. of water, to which 42.75 gm. of fuller's earth were added. There was no effect whatever, excepting that the animal refused food and drink for several hours afterward. During the succeeding days the animal was perfectly normal. Its bowel movements were hard and clay-colored lumps. Its urine was free from albumin. The animal was chloroformed five days afterward. Its gastro-intestinal tract was found normal. Identical results were obtained in three other dogs. On the other hand, one dog whose stomach was full of food vomited shortly after administration of the dose, probably from overdistention of the stomach. Two other dogs recovered from twice the surely fatal dose of fluidextract of ipecac, namely, 3 c.c. of the fluidextract per kilogram, diluted with ten times the amount of water to which a proportionate amount of fuller's earth had been added. Both dogs had a single emesis soon after injection, probably from overdistention of the stomach, for the bulk of the dose is considerable; but developed no further results of any importance and recovered completely, as may be seen from the protocol of one of these experiments:

A dog, weighing a little less than 12 kg., was given 35 c.c. of fluidextract of ipecac with 350 c.c. of water and 14 gm. of Lloyd's reagent. The dose was administered at 9:50 a. m. Shortly afterward, profuse salivation appeared and lasted for over an hour. Twenty minutes after the injection a single emesis occurred, the vomit consisting of thin watery fluid with a small amount (3 gm.) of the injected preparation. There was no further emesis. A fine muscular tremor appeared at 12 m., and lasted about an hour. Complete recovery took place.

Evidently fuller's earth is a powerful antidote to ipecac. To test its practical value in case of poisoning, the antidote was administered at varying intervals of time after the introduction of the poison with results that might best be shown by tabulation.

It will be noted (Table 9) that, when the fuller's earth was given mixed with the poison, no damage occurs.

When the fuller's earth was given ten minutes afterward, the animal was seriously affected by the poison, but recovered. Fuller's earth was incapable of saving animals when administered twenty minutes or longer after the poison; but it rendered the picture of intoxication milder and postponed death in inverse proportion to the length of time that elapsed between the administration of the poison and of the antidote.

ANTIDOTAL VALUE IN ACONITIN POISONING

Table 10 shows that fuller's earth has some antidotal value in this condition also. It is difficult, however, to arrive at a definite judgment as to the degree of its value. It produces emesis even after the previous administration of morphin. That the emesis does not save life, will be seen from the fact that all the dogs that died vomited. They generally vomited more profusely than the dogs that recovered. Therefore emesis was probably not a factor in those cases in which recovery took place. It will be noted that in practically all the animals that did recover rather marked symptoms occurred: emesis generally the next day, and in several of them bloody defecation, which in one case lasted for several days. The death of the animal D 5 may not have been due to the poison, as the animal was sick before it was subjected to the experiment, as was discovered subsequently. In another series of animals, in which the alkaloid aconitin (crystallized) was used—not the salt—death occurred in every case, even when fuller's earth or fuller's earth with acid were added, the fatal result being postponed for from twenty-four to forty-eight hours. Evidently the free alkaloid does not combine with fuller's earth as readily as does the salt.

TABLE 9.—RESULTS OF ADMINISTRATION OF FATAL DOSE (1.5 C.C. PER KG.) OF FLUIDEXTRACT OF IPECAC, WITH AND WITHOUT FULLER'S EARTH AT VARYING INTERVALS

Dog	Administration	Emesis		Defecation	Result	Post-Mortem Examination
		Onset, Min.	Times			
A	Ipecac............	138	5	Bloody.....	Death in 24 hours.	Violent gastro-enteritis.
E	Ipecac............	...	0	Liquid not bloody.	Death in 5 hours.	Gastro-intestinal tract pale.
F	Ipecac and fuller's earth 40 minutes later.	...	0	Liquid not bloody.	Death within 20 hours.	Gastro-enteritis.
G	Ipecac and fuller's earth 30 minutes later.	55	6	Bloody.....	Death in 25 hours.	Gastro-enteritis.
H	Ipecac and fuller's earth 20 minutes later.	70	1	Bloody.....	Death within 44 hours.	Less severe gastro-enteritis.
I	Ipecac and fuller's earth 10 minutes later.	22	13	Bloody.....	Aborted 5 fetuses. Lived for 5 days.	Gastro-intestinal tract showed evidences of past enterocolitis.
J	Ipecac and fuller's earth mixed.	...	0	Hard, clay-colored.	Recovery....	Gastro-intestinal tract normal.

TABLE 10.—EFFECT ON DOGS OF FATAL DOSE OF ACONITIN NITRATE, CRYSTALLIZED (MERCK'S), (4 MG. PER KILOGRAM), GIVEN ORALLY, WITH AND WITHOUT FULLER'S EARTH AND ACID

Dog		Morphin Sulph., 5 mg. per kg. Hypo. 1 Hour Prev. Gm.	Dose			Effects	
No.	Weight, Gm.		Aconitin	Fuller's Earth	NaH_2PO_4	Symptoms	Result
A 1	6,350	0.032	0.0254	0	0	Profuse emesis in 5 min.	Death in 50 min.
A 2	5,096	0.025	0.0204	0	0	Conv., emesis in 4 hours.	Death in 5 hrs.
B 1	8,600	0.043	0.0344	17.20	.....	0	Recovery.

D 5	7,250	0.036	0.0290	14.50	14.50	Emesis in 1:30 hours.	Death in 44 hrs.

TABLE 11.—EFFECT ON DOGS OF FATAL DOSES OF COLCHICIN (2 MG. PER KILOGRAM), *GIVEN ORALLY, WITH AND WITHOUT* FULLER'S EARTH AND ACID

Dog		Dose				Effects	
No.	Weight.	Preliminary Morphin, 0.005 per Kg.	*Colchicin*	*Fuller's* Earth	*Acid*	Symptoms	Results
A 1	19,500	0	0.039	0	0	Vomiting in 1:30 hours. Bloody defec. in 4:30 hours.	Death with violent gastritis and colitis within 20 hrs.
A 2	7,700	0.0375	0.0155	0	0	Vomiting and bloody defec. next day.	Death with violent gastritis and colitis in 30 hours.
D 1	9,300	0.050	0.0186	5.60	5.60 NaH_2PO_4	Bloody defec. next day.	Death with less severe colitis in 68 hours.

ANTIDOTAL VALUE IN COLCHICIN POISONING

The antidotal value of fuller's earth against colchicin poisoning is, no doubt, very slight, even though the number of experiments on this point, as shown by Table 10, may be insufficient. With the comparative indifference, however, of colchicin toward fuller's earth, as shown in Table 2, a different result could hardly be expected.

PERSONAL EXPERIMENTS WITH METHYLENE BLUE AND FULLER'S EARTH

To put the question to an approximate test whether fuller's earth would be likely to act in human beings as it does in the lower animals, I and one of my colleagues took doses of methylene blue with and without fuller's earth with the following results:

When a dose of 0.010 gm. of methylene blue is taken a dark green color appears in the urine within a short time and disappears within twenty-four hours. If 1.0 gm. of fuller's earth is added to 0.010 gm. of methylene blue in solution, the urine acquires a faint greenish tint for twenty-four hours; the difference between the two specimens of urine being striking.

The results of larger doses might probably best be presented as in Table 12.

It will be noted that fuller's earth alone postponed the appearance of the discoloration, lessened the duration of intense discoloration, but not the duration of slight discoloration. The addition of a small amount of sodium dihydrogen phosphate did not increase very greatly the effect of fuller's earth. The addition of a larger dose that acted on the bowel within an hour and thirty minutes markedly lessened the period and amount of discoloration. It seems safe to conclude that *fuller's earth, especially when combined with a laxative dose of sodium dihydrogen phospate, is capable of greatly lessening in the human the absorption of substances that are readily adsorbed by fuller's earth.*

CONCLUSIONS

1. Alkaloidal fuller's earth compounds do not act on the stomach; but are gradually dissociated in the intestine, producing a delayed and milder general action.

2. Fuller's earth has antidotal value in morphin, cocain, nicotin, and ipecac poisoning. It has less value in strychnin and in aconitin poisoning, though even in these conditions it is capable of saving life, when combined with sodium dihydrogen phosphate. In colchicin poisoning it is of little value.

3. The power of adsorbing alkaloids is strongly developed in some fuller's earths and very feeble in others. The adsorptive value of commercial fuller's earths should be stated by the dealers; and pharmacists should demand specimens of high activity. Lloyd's reagent possesses this power to the highest degree.

4. Fuller's earth is not synonymous with kaolin, as the United States Dispensatory and the National Dispensatory would lead one to infer. It is a substance with markedly different properties.

TABLE 12.—RESULTS OF DOSES OF METHYLENE BLUE WITH AND WITHOUT FULLER'S EARTH AND SODIUM DIHYDROGEN PHOSPHATE

Experiment	Dose	Effect
1	0.050 gm. methylene blue	Urine green in 1 hr. 25 min., lasting for 2½ days.
2	0.050 gm. methylene blue 2.500 gm. fuller's earth..	Urine green in 9 hrs., lasting for 24 hrs. Traces of discoloration occasionally for 2 days longer.
3	0.050 gm. methylene blue 2.500 gm. fuller's earth.. 2.500 gm. NaH_2PO_4......	Urine green in 10 hrs. 30 min., lasting for 17 hrs. Traces of discoloration occasionally for 2 days longer.
4	0.050 gm. methylene blue 2.500 gm. fuller's earth.. 5.000 gm. NaH_2PO_4......	Bluish brown liquid defecation in 1 hr. 30 min. Urine light green in 10 hrs. Urine green in 14 hrs., lasting for 7 hrs. Traces of discoloration occasionally for 12 hrs. longer.

CHRONIC APPENDICITIS, PYLOROSPASM AND DUODENAL ULCER

A PRELIMINARY NOTE *

CHARLES D. AARON, Sc.D., M.D.
Professor of Gastro-Enterology, Detroit College of Medicine and Surgery
DETROIT

Two years ago I called attention to the fact that in chronic appendicitis, though unsuspected, a continuous firm pressure with the ends of the first three fingers over McBurney's point frequently induced distress or pain in the epigastrium.[1] Recently, while examining a case of chronic appendicitis with the Roentgen fluoroscope, I was surprised to find that I was able to induce a pylorospasm by this pressure over the appendix. The pressure also produced the reflex pain in the epigastrium of which the patient complained. I am inclined to believe that this pain was due to spasm of the pylorus.

I wish to report the following case:

Miss L., aged 23, American, with negative family history, had had mastoiditis on the left side two years before. She had stomach trouble for three or four years, with an acute attack, sixteen months before, of epigastric pain and nausea, not associated with jaundice or vomiting. For the past eight months she had complained of a pressing sensation in the upper abdomen occurring about thirty minutes after eating. This sensation was accompanied by eructations and was somewhat relieved by the taking of food.

The physical examination showed a well-nourished young girl, presenting only epigastric pain on deep pressure over McBurney's point.

With the Roentgen fluoroscope it was seen that the bismuth and buttermilk introduced tended to remain in the upper pole of the stomach. The walls of the stomach were parallel; the pyloric portion was well outlined; there were good contractures, and the duodenal cap was well formed and pointed upward. Pressure over the appendiceal region caused a spasm of the lower quarter of the stomach and the first portion of the duodenum. This contraction was so pronounced that it prevented the passage of the bismuth meal through the spastic areas. On releasing the pressure, we noticed that the pylorus and duodenum relaxed and the bismuth could be plainly seen passing through the pyloric canal and the first portion of the duodenum into the second and third portions of the latter.

If this demonstration can be confirmed, I believe it will be found of considerable importance, as pointing the way in which we can utilize reflex spasm of the stomach and duodenum in diagnosing disease in a remote part of the abdomen.

This phenomenon of spasm of the pylorus and first portion of the duodenum induced by pressure in the appendicular region is easily understood when we recall that the appendix has a rich nerve connection derived from the superior mesenteric plexus of the sympathetic, and from the cardiac, hepatic and gastric plexuses. Therefore any irritation originating in the appendix will readily send impulses to the other viscera. Because of the direct nerve connection between the appendix, pylorus and duodenum, it follows that a chronic appendicitis may induce over this arc a reflex gastrospasm, pylorospasm or enterospasm.

If it be granted that the pain elicited in the epigastrium by pressure over the appendiceal region in chronic appendicitis is due to pylorospasm caused by such pressure, the etiology of the gastric symptoms and the hyperchlorhydria associated with appendicitis is clear.

In the case reported we have an interesting demonstration of what we have long believed, that the gastric distress, eructations and other symptoms of appendicitis are due to pylorospasm.

It may be that this will suggest an explanation for the cause of the frequent occurrence of duodenal ulcer in chronic appendicitis, on the basis that the associated spasm of the pylorus and first part of the duodenum induces an ischemia, which allows the gastric juice to attack the mucosa, the resistance of which has been lowered.

XXI

DIAPHORETICS

One of the functions of the sweat glands is to provide moisture, which by its evaporation cools the body, the secretion of sweat being increased when the production of heat by the body is increased.

This secretion is controlled largely by the heat regulating centers, and when the blood flowing through the carotids is warmed it causes an increased secretion, as does the warming of the surface of the body also.

The activity of the sweat glands is influenced less by the blood supply than is that of most of the glands of the body, and profuse sweating may occur when the skin is pale, and, on the other hand, there may be little secretion when the skin is flushed and hot in fever. However, heat increases the excitability of the nerve endings in the sweat glands and an abundant supply of blood often promotes the secretion.

The composition of the sweat and the daily amount secreted varies widely under normal conditions, and still more widely under pathologic conditions.

The amount of sweat secreted in twenty-four hours by a healthy man with light exercise probably does not often fall below 500 c.c. (1 pint), but with hard work during hot weather the secretion may become more than ten times as active, and under pathologic conditions, as during sudden collapse, the amount secreted in a few minutes may equal the amount which is secreted in an entire day under ordinary conditions.

The sweat contains small amounts of salts, of which sodium chlorid constitutes much the larger amount, and usually only insignificant amounts of organic matter, but when the activity of the glands is greatly increased, during severe muscular exercise or by hot vapor baths, the amount of organic matter is increased notably, and when the kidneys become incapable of secreting urea as fast as it is formed, so that it accumulates in the blood, a considerable amount is found in the sweat, and it is commonly stated that crystals of urea sometimes may be found on the skin under those conditions.

It seems probable that one of the functions of the sweat glands is to provide a means of eliminating water from the blood without a corresponding loss of its salts, but when the loss of water from the blood is made up by absorption either from the gastro-intestinal tract or from the tissues, the loss of salts may be important, and the blood may then have a lower concentration than before active sweating was induced. From this it would seem that the sweat glands supplement the action of the kidneys to an important degree.

Sweating also serves to remove large numbers of bacteria from the deeper layers of the skin, and it is probable that with the profuse sweating of exercise that this action is not without importance.

The methods of inducing active sweating without the use of drugs do not call for discussion in this place; the actions of the analgesic antipyretics and various vasodilators have been discussed elsewhere.

PILOCARPIN

Pilocarpin stimulates all parasympathetic nerve endings and the sympathetic nerve endings in the sweat glands, which, as previously stated, behave toward several drugs like the parasympathetic.

The sweating begins in about fifteen minutes and lasts about two hours. The stimulation of the chorda causes profuse salivation, while the secretion of the bronchial glands may embarrass respiration, and pilocarpin is therefore contra-indicated in patients in whom there is a predisposition to edema of the lungs.

Pilocarpin stimulates the vagus endings, causing moderate slowing of the heart rate, but the action differs essentially from that of digitalis, for the stimulation resulting from small doses tends to pass into depression so that the heart rate increases, and when large doses have been administered the stimulation is brief and the depression almost as great as that resulting from atropin. Hence it is impossible to induce an important degree of slowing of the heart by doses of pilocarpin.

The action of physostigmin resembles that of pilocarpin qualitatively, but it is so much more depressant than pilocarpin to the central nervous system in doses producing an equal diaphoretic effect that it is never used for that purpose.

THERAPEUTIC USES

Sweating serves to increase the concentration of the blood, thus promoting the absorption of dropsical effusions if the amount of water ingested is restricted sufficiently.

Profuse sweating serves to remove a certain amount of various substances which are usually excreted by the kidneys, and while the amount of nitrogenous matter normally excreted in the sweat during rest is insignificant, a much larger amount is excreted during profuse sweating.

The amount of urea eliminated during even profuse sweating would seem to be too small to account for the improvement which results from sweat baths in nephritis and uremic poisoning, hence one cannot say to what the improvement is attributable. It is possible that the removal of chlorids from the blood may relieve the kidney, for, as previously stated, sodium chlorid is actually injurious to the kidneys under certain circumstances.

It is popularly supposed that other toxic substances are excreted in this way, but our knowledge of this subject is as yet very imperfect.

A popular treatment of "colds" consists in the use of large quantities of hot lemonade while the body is kept warm to induce sweating. A hot mustard foot bath is commonly taken at the same time, and this treatment frequently results in the disappearance of the symptoms, probably because the alteration in the distribution of the blood which is induced relieves the local congestion in the nasal passages.

The same objects are often accomplished by the use of the compound powder of ipecac and opium and the mustard foot bath, or by a hot bath taken just before retiring in a warm room; this induces active sweating which continues for some hours, if the patient is kept warmly covered.

Chronic rheumatism and gonorrheal arthritis are often treated by placing the affected limb in a hot-air chamber for half an hour, while maintaining a temperature of from 70 to 90 C. (150 to 180 F.).

---

* This is the twenty-first of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

A limb, or even the whole body except the head, may be subjected to a high temperature for a short time if care is taken to provide for a sufficient circulation of air to insure the evaporation of water as fast as it is eliminated in the sweat. Heating a limb or the body causes the body temperature to rise—sometimes as much as several degrees—and cold water or an ice bag should be applied to the head to prevent the effects on the brain which would ensue.

Solution of ammonium acetate and spirit of nitrous ether are commonly used as diaphoretics during fevers, but their action is feeble, and we have many better means of inducing sweating.

Pilocarpin is used as a diaphoretic in certain diseases of the skin, and it is generally credited with the property of stimulating the growth of the hair, but failure is far more common than success when it is used in baldness.

Doses just short of that required to induce sweating are sometimes used to relieve itching in generalized acute eczema, urticaria and other conditions. Its use as a miotic has been discussed.

Pilocarpus owes its therapeutic effects to the pilocarpin which it contains, but it also contains pilocarpidin, which has an atropin action, hence it would seem that there is never any occasion to use the crude drug rather than pilocarpin.

DOSAGE

The diaphoretic dose of the compound powder of ipecac and opium is 0.6 gm. (10 grains); the dose of the hydrochlorid or nitrate of pilocarpin is from 0.001 to 0.01 gm. (1/60 to 1/6 grain).*

EVACUANTS

Drugs that are used to cause evacuation of the bowels are variously classified; according to their origin and chemical nature; according to the intensity of their action, and according to their general mode of action. The term laxative is applied to those which cause a nearly normal movement of the bowel, attended with little or no pain; if the action is much more vigorous and several movements are induced, the term purgative or cathartic is employed; and when a large amount of fluid is evacuated with the feces the action is termed drastic, or hydragogue.

For practical purposes it will be convenient to discuss the evacuants with reference to the part of the intestine on which they exert their main action, for a drug may be laxative or drastic, dependent on the dose employed and other conditions, and evacuants must be chosen with strict regard to their mode of action and the seat of this action.

The processes of digestion are so closely related to the intestinal movements that a brief discussion of the physiology of the gastro-intestinal tract is indispensable for a clear presentation of the subject of evacuants.

The stomach is an automatic organ, containing within its walls the plexuses of Meissner and Auerbach, on which its automaticity probably depends; at any rate the surviving excised stomach is capable of maintaining regular movements, and the processes of secretion of gastric juice may take place after the connection with the central nervous system has been severed, but the stomach is influenced both as to movements and secretions, by two sets of nerves from the central nervous system, the parasympathetic (vagus), the functions of which are here mainly motor, and the sympathetic (splanchnic) which is mainly inhibitory. The control of these two nerves is so coordinated that when one of them is stimulated the other is usually depressed.

The functions of the stomach are to secrete the gastric juice and to maintain movements which serve to mix the food with this juice and to drive the digested food into the intestine.

The length of time during which food remains in the stomach varies with the nature of the food, and it may be influenced greatly by drugs. Proteins are digested more slowly than carbohydrates, and fats pass still more slowly into the intestine, and if they be taken before proteins and carbohydrates they delay their passage through the pylorus.

The sphincter of the pylorus relaxes periodically to allow the fluid portions of the stomach contents to pass into the intestine. An alkaline reaction in the duodenum promotes, an acid reaction delays, this relaxation, but when water or a dilute solution of a salt is taken during digestion, it passes along the lesser curvature of the stomach, and reaching the pylorus without mixing with the rest of the stomach contents, passes rapidly into the intestine. This is of some practical importance with reference to the action of certain of the purgatives.

Strong stimulation of the vagus, such as toxic doses of morphin induce, cause spasmodic contraction of the pylorus and the passage of the stomach contents may be delayed indefinitely. Stimulation of the splanchnic causes cessation of the movements of the normal stomach and relaxation of the pylorus, but such stimulation of the splanchnic cannot overcome strong vagus stimulation. In such cases depression of the vagus is more effective, hence atropin is used to lessen excessive movements of the stomach in gastric ulcer. This also serves to explain why large doses of morphin are contra-indicated in that condition, but small doses, sufficient to lessen pain, may be used, for the gastric effects of vagus stimulation are not usually elicited from less than 10 mg. (1/6 grain), while half that amount exerts a marked analgesic action.

Atropin is not so effective in quieting the movements of the stomach when these are due to diminished tone of the splanchnic, for then the automatic mechanism alone suffices to increase the activity of the movements and depression of the vagus is then of little value. Unfortunately, we have no drug which is of much use in increasing the tone of the sympathetic, unless it be ergot.

The mechanism controlling the activities of the intestines is much like that of the stomach. Peristaltic movements in the intestine consist of waves of contraction preceded by relaxation of the musculature of the wall; these are automatic, but they are influenced by parasympathetic (vagus) and sympathetic (splanchnic) nerves.

The function of the parasympathetic nerve to the intestine is mainly motor and that of the sympathetic is mainly inhibitory, as in the stomach, but it seems probable that there are some inhibitory fibers in the vagus, and some motor fibers in the sympathetic. The vagus is distributed to the intestine as far down as the descending part of the colon, where its place as a parasympathetic motor nerve is taken by the erigens, on which atropin and some other drugs act in the same way that they do on the vagus, but less effectively. The nerves which supply the colon and rectum also supply the uterus, which explains in part the effect of certain purgatives on that organ.

---

* On account of lack of space the materia medica of this group is omitted from THE JOURNAL. It will be included when the series is published in book form.

Stimulation of the parasympathetic (vagus or erigens) nerve to the intestine causes active peristalsis, and strong stimulation of certain centers in the medulla is followed by diarrhea. The intestinal movements are also subject to psychic influence, but the mechanism of this is not understood. It is possible that the intestinal peristalsis which accompanies certain emotions may be due in part to an increase of carbon dioxid in the blood, this increase being due to respiratory depression, for carbon dioxid and hydrogen sulphid are normal stimuli to the intestine, causing peristalsis.[1]

The movements of the large intestine differ considerably from those of the small. The contents of the colon are forced along to the descending part because of overfilling from the ileum, and such movements as occur in the ascending and transverse portions are in the reverse direction, serving to keep the contents thoroughly mixed and promoting absorption. In the descending colon the contents are driven very slowly toward the rectum by means of peristaltic movements much like those in the small intestine. It is uncertain whether the rectum normally contains fecal matter except just before defecation, but there is no reason to doubt that its distention by feces causes a desire to go to stool. The retention of feces in the rectum may lead to dilatation, and the development of a form of chronic constipation.

Anything which increases the bulk of the intestinal contents will promote intestinal peristalsis, for this distention of the intestine seems to be one of the chief stimuli to the automatic mechanism. The fluid contents of the intestine may be increased by augmented gastric or intestinal secretion, or by diminished absorption from the intestine into the circulation.

Estimates of the total amount of fluid secreted by the different digestive organs vary considerably, but it may be accepted that from 3 to 5 liters (from 6 to 10 pints) of fluid are secreted daily by the salivary, gastric and intestinal glands and the pancreas and liver together, and that nearly all of this, together with the liquefied food, enters the small intestine, and a large part of this reaches the colon. From this it is evident why so much fluid may be removed from the body by even a mild, but rapidly acting, evacuant. The composition of the blood can be altered rapidly in this way, and especially by those cathartics which stimulate the intestinal glands to increased secretion. With the changes in the composition of the blood thus induced are associated corresponding changes in the secretions and excretions throughout the body, for most of the glands are influenced profoundly by the composition of the blood, as well as by changes in the amount with which they are supplied.

The passage of fluid through the small intestine requires from eight to twenty hours, as a rule (only a few minutes in some conditions of hyperexcitability of the intestine), and the passage through the large intestine requires a shorter period, during which active absorption of fluid takes place, leaving the fecal mass composed mainly of bacteria, undigested food particles, such as the lignin of vegetables, detritus of the intestine, and various principles in small amount, together with enough moisture to make it plastic.

If the intestinal movements are unduly sluggish, opportunity is afforded for the absorption of too large a proportion of fluid, the feces become hard, dry and difficult to propel by the normal peristaltic movements, and it becomes necessary to soften such masses before they can be evacuated.

There are various physiologic ways of preventing this sluggishness of the intestinal movements, and it is obvious that such means should be tried before resorting to the use of drugs. The taking of an adequate amount of cold (not iced) water between meals affords the simplest means of hastening peristalsis in the small intestine, and thus indirectly, in the large, for, as previously stated, when water is taken during digestion it passes rapidly into the intestine, and probably even more rapidly if taken when the stomach is empty.

Some stress is placed on the taking of this cold water between meals, rather than with them, for secretion of the digestive fluids depends to some degree on the amount of fluid in the circulation and tissues. If a normal amount of the digestive secretions is available it supplies the fluid which is requisite for normal peristalsis, and it is only when this has been absorbed, at least in large part, that the additional water taken between meals is required to maintain the bulk of intestinal fluid which is required for active peristalsis.

Some stress is also placed on the use of cold water rather than hot fluids, such as tea and coffee, for hot fluids promote rapid absorption from the small intestine and even less fluid will then reach the colon. It seems probable that the constipating effect which tea and coffee often exert is due in part to the fact that the rapid absorption of fluid from the small intestine induces active diuresis, which is further augmented by the action of the caffein which they contain, and that this diuresis increases the viscosity of the blood, which in turn diminishes the gastric and intestinal secretions, the increased absorption from the intestine, and the diminished secretion into it cooperating to deprive the intestine of its normal stimulus to peristalsis.

A glass of cold water taken on rising is often sufficient to cause prompt evacuation of the bowels.

Laxatives increase the peristalsis slightly and the feces are evacuted before they become dehydrated in the colon.

Many persons eat too little habitually, and without advocating an excessive diet, it is a matter of common observation that one who suffers from mild chronic constipation associated with a spare diet will often have a normal stool soon after taking a large meal.

It is often urged that a part of the food should not be too readily digestible, and while it is true that indigestible food does promote peristalsis, it does not appear to be necessary, provided that the diet is abundant.

A good appetite, which insures the taking of a fairly large amount of food, and good digestion, which insures the secretion of an adequate amount of fluid in the gastro-intestinal tract, are far more effective in securing active peristalsis than a small amount of indigestible food would be, for undigested food constitutes only an insignificant part of the normal intestinal contents, and furthermore, soft indigestible matter always invites the activity of pathogenic micro-organisms.

---

[1] Certain emotions, such as fear, exert two types of action in different individuals; in one type the effects are referable to stimulation of the sympathetic, and include high blood pressure and inhibition of the gastro-intestinal movements; in the other their effects are referable in part to stimulation of the parasympathetic nerves, and include low blood pressure and active movements of the gastro-intestinal tract.

An ideal cathartic should pass through the stomach without disturbing it and exert its action on the intestine without causing pain or inflammation, and these conditions must be approximated in order that a drug may be of any use as an evacuant of the intestine.

We are in need of an evacuant which is suitable for subcutaneous injection, and which will then produce purgation without giving rise to excessive irritation at the point of injection, or irritating the kidneys. None of the agents which we use as cathartics is well adapted for therapeutic use by subcutaneous injection, some being local irritants, others having undesired side actions.

(To be continued)

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

PAPAVERINE.—$C_{20}H_{21}O_4N$.—An alkaloid obtained from opium, belonging to the benzyl iso-quinoline group (i. e., it is not a morphine derivative).

Actions and Uses.—Pal found that papaverine relaxes smooth muscle in general—although different organs are affected in a varying degree.

Papaverine is most effective in hypertonic conditions, while it does not interfere materially with the normal movements, for instance of the intestines. It is also a rather feeble central analgesic and a local anesthetic. Its toxicity is low, and neither tolerance nor habituation has been reported. These actions have prompted its use, with reported success, in various spasmodic conditions of the smooth muscles. Pal recommends it especially in all kinds of gastric and intestinal spasms (also for the diagnosis of pyloric spasm); in biliary colic; and in bronchial spasm. Of more doubtful value is its employment in pertussis, hyperemesis, and vascular spasm — angina pectoris, acute uremia and eclampsia. It is admitted to be ineffective in chronic hypertonus. The local anesthetic action, with vasodilatation, has been used against rhino-asthma, and to mitigate the pain of irritant injections.

Dosage.—The oral and hypodermic single dose is 0.03 to 0.08 Gm. (½ to 1¼ grains); daily dose to 0.5 Gm. Single doses of even 1 Gm. are said to be non-toxic.

Papaverine occurs in fine, white rhombic prisms or needles or sometimes in scales; odorless and tasteless.

Papaverine is nearly insoluble in cold water; very sparingly soluble in alcohol, ether, chloroform and benzene if cold; somewhat more soluble in these liquids when hot, but deposited by them on cooling; soluble in warm petroleum ether and in acetone.

Papaverine melts at 147 C.

If about 0.01 Gm. of papaverine be dissolved in 10 Cc. of water containing a few drops of diluted hydrochloric acid, and a few drops of potassium ferricyanide solution added, a lemon-yellow precipitate of papaverine ferricyanide should form at once (distinction from *other opium alkaloids*).

If about 0.001 Gm. of papaverine be dissolved in 0.1 Cc. of sulphuric acid containing in each c.c. one drop of formaldehyde solution, a colorless solution, or at most a faintly yellowish-green color, should be produced; this gradually changes to deep rose and finally becomes brown (distinction from *morphine and its esters*, which give purple or violet colors).

If 0.01 Gm. of papaverine be dissolved in 0.2 Cc. of sulphuric acid the solution should not be colored more than very faintly pinkish or brownish (limit of *cryptopine, thebaine or of other organic impurities*).

If 0.01 Gm. of papaverine be dissolved in 10 Cc. of water containing a few drops of hydrochloric acid, a few drops of a saturated aqueous solution of iodic acid added, and the mixture shaken with chloroform, the chloroform layer should not be colored violet (absence of *morphine*).

If from 0.2 to 0.3 Gm. of papaverine be weighed, dissolved in 20 Cc. of warm water containing a few drops of diluted hydrochloric acid, the solution cooled, 1 Cc. of freshly prepared potassium ferricyanide solution added, the mixture agitated, allowed to stand over night, filtered, the filtrate made alkaline with ammonia water, shaken with several successive portions of ether, the ether solutions combined, washed with water, evaporated, the residue dried at 100 C. and weighed, the weight should not amount to more than 2 per cent. of the weight taken (limit of *foreign opium alkaloids*).

PAPAVERINE HYDROCHLORIDE.—Papaverinae Hydrochloridum.—$C_{20}H_{21}O_4N.HCl$.—The hydrochloride of the alkaloid, papaverine, containing not less than 88 per cent. of papaverine.

Actions and Uses.—See papaverine.

Dosage.—See papaverine.

Non-Proprietary Preparations:

Papaverine Hydrochloride, Merck.—Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

Papaverine Hydrochloride, Roche.—Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (Hoffmann-LaRoche Chemical Works, New York City).

Papaverine Hydrochloride, Roche, Tablets.—Each tablet contains papaverine hydrochloride, 0.04 Gm.

Papaverine hydrochloride occurs in a fine white, crystalline powder or in small monoclinic plates or prisms; odorless and having a bitter taste; permanent in the air.

Papaverine hydrochloride is sparingly soluble in water; soluble in alcohol; very soluble in chloroform; insoluble in ether.

An aqueous solution of papaverine hydrochloride has an acid reaction toward litmus paper.

If from 0.2 to 0.3 Gm. of papaverine hydrochloride be weighed, dissolved in 20 Cc. of warm water, the solution cooled, a slight excess of ammonia water added and the mixture shaken with three successive portions of 25 Cc. each of ether, or a sufficient quantity to complete the extraction, the ether solutions combined, washed with water, evaporated to dryness, the residue dried to constant weight at 100 C. and weighed, the weight should indicate not less than 88 per cent. of papaverine. The alkaloid obtained by this process should conform to the tests for identity and purity described under Papaverine.

PAPAVERINE SULPHATE.—Papaverinae Sulphas.—$(C_{20}H_{21}O_4N)_2H_2SO_4$.—The sulphate of the alkaloid, papaverine, containing not less than 85 per cent. of papaverine.

Actions and Uses.—See papaverine.

Dosage.—See papaverine.

Papaverine Sulphate, Roche, Ampules.—Each ampule contains papaverine sulphate solution equivalent to 0.04 Gm. papaverine sulphate. Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (Hoffmann-LaRoche Chemical Works, New York City).

Papaverine sulphate occurs in white, crystalline powder; odorless and having a bitter taste; slightly hygroscopic.

Papaverine sulphate is soluble in water and in alcohol; very soluble in chloroform; insoluble in ether.

An aqueous solution of papaverine sulphate has an acid reaction toward litmus paper.

If from 0.2 to 0.3 Gm. of papaverine sulphate be weighed, dissolved in 20 Cc. of water, a slight excess of ammonia water added and the mixture shaken with three successive portions of 25 Cc. each of ether, or a sufficient quantity to complete the extraction, the ether solutions combined, washed with water, evaporated to dryness, the residue dried to constant weight at 100 C. and weighed, the weight should indicate not less than 85 per cent. of papaverine. The alkaloid obtained by this process should conform to the tests for identity and purity described under Papaverine.

For a Flyless Town.—The *Bulletin* of the health department of Chicago for April 3 says it is known that 90 per cent. of flies breed in horse manure, and if the manure pile could be gotton rid of the 90 per cent. of flies would vanish and the other 10 per cent. could easily be taken care of. The present ordinance regulating the manure problem would, if enforced, go far toward making Chicago a flyless city. Attempts have been constant to enforce it and over 6,000 notices were given and 1,500 suits were brought last year to abate manure nuisances, many of which suits have not been reached on account of congestion of the courts.

TETANUS CARRIERS

It is thirty years since Nicolaier succeeded in producing tetanic symptoms in animals by inoculating them with soil. The micro-organisms responsible for this result are now known to occur in the superficial layers of the earth's surface. One bacteriologist has reported that soils from thirty-eight cities in different parts of the world were tested by him and that positive evidence of the tetanus bacteria was obtained from all except twelve of the cities. The fact that the soil of cultivated and manured fields seems to harbor the *Bacillus tetani* with especial frequency has been attributed to the probable presence of this germ in the dejecta of some of the domestic animals. Indeed, this is more than a mere supposition, since the bacillus has been found by some to be particularly abundant in the feces of horses. Pizzini[1] even asserted that he had found it in 5 per cent. of the human feces examined; with the added indication that whereas 30 per cent. of the men working about horses and stables have tetanus bacilli in their feces, only 2.2 per cent. of men engaged in other occupations have them.

The tetanus organism is so prominent as a danger to mankind that the problems of its sources and distribution become of the utmost importance. This is intensified by the unusual viability of the spores of this species. Protected from sunlight and other deleterious influences, they may remain virulent for many years. A case has actually been reported in which tetanus was produced with bacilli from a splinter of wood infected eleven years before.[2] The comparative infrequency of tetanus infection in ordinary life does not in any way minimize the wide distribution of the exciting organism in nature.

From observations made in the laboratories of the Sheffield Scientific School of Yale University, Noble[3] has reached the conclusion that the tetanus bacillus appears in the intestines of many normal animals, especially of the herbivora. Apparently it is impossible, with the current technic available, to detect the micro-organism unless it is present in relatively large numbers. Park[4] states that 15 per cent. of horses and calves in the vicinity of New York City harbor tetanus bacilli in their intestines. Noble found that eleven out of sixty-one horses examined, or 18 per cent., showed this organism in their feces. He failed to find them in the excreta of cows; but the investigations on this species were not conclusive, because they were made on a herd of cattle confined in a barn during the winter months when the diet of ensilage was such as to exclude the probability of its containing tetanus spores.

Noble is inclined to the belief that the tetanus bacillus may multiply within the intestines of suitable animals. Some of these seem to offer especially favorable conditions for this growth. Tests on two selected horses showed that the tetanus spores disappeared from the feces of one fourteen days after the beginning of the observations; whereas the other animal harbored them continuously for four months, although, here too, they eventually disappeared. It is highly improbable that this persistence was due to repeated reinfection, because other horses in the same stable showed no signs of fresh invasion by the tetanus bacilli.

If these observations are valid in demonstrating that individual horses may harbor tetanus bacilli in their alimentary tract for many months following an initial infection, the phenomenon would appear to present the case of a "tetanus carrier" comparable with the well-known typhoid carriers and other seemingly healthy disseminators of human infection. How common the "tetanus carriers" may be among horses remains to be ascertained; but, as Noble contends, if we grant their existence, the universal distribution of tetanus spores is not difficult to explain. In any event, the presence of these forms in soils, street dust, fresh vegetables, on the clothing and the skin is easily attributable to fecal contamination, as has so often been maintained.

MENTAL CHANGES IN EXOPHTHALMIC GOITER

It is well known that the mental condition of patients with exophthalmic goiter is frequently not normal, and that a loss of balance of the nervous and psychic equilibrium is one of the first signs of beginning thyroid intoxication. Since these mental disturbances often become prominent, they have received much attention under the title of the "Basedow psychosis."

Léopold Lévi and Rothschild call the thyroid the "glande de l'émotion," and refer to the mental status of exophthalmic patients as a "hyperthyroid temperament." Homburger believes that exophthalmic goiter and the accompanying mental derangements are related in that they spring from a common ground, there being a neuropsychopathic anlage. In six epileptics suffering with exophthalmic goiter, the influence of the latter disease on concomitant psychic disturbances was marked. Many other writers refer to a relation between psychoses and exophthalmic goiter.

[1] Pizzini: *Baumgarten's Jahresb.*, 1894, xiv, 236.

[2] Henrijean: Ann. Soc. méd. chir. de Liége, 1891.

[3] Noble, W.: Experimental Study of the Distribution and Habitat of the Tetanus Bacillus, *Jour. Infect. Dis.*, 1915, xvi, 132.

[4] Park, W. H.: Pathogenic Bacteria and Protozoa, 1910, p. 232.

The most conclusive proof of relationship lies in a parallelism between the two disorders. As the usual symptoms of exophthalmic goiter increase in severity, the psychosis becomes more marked; as the symptoms improve, the psychosis improves, and if the patient recovers entirely from the goiter, the psychosis likewise disappears. In a series of eighty-six cases of exophthalmic goiter collected by Pharon,[1] he holds the goiter responsible for the accompanying psychosis in sixty-seven instances because of this parallelism. Among these cases were many manic-depressive and psychasthenic individuals. Colla[2] found a similar parallelism in a series of goiter cases compiled for an entirely different purpose. He had under observation two patients who, after having had a Basedow neurosis for some time, finally developed an exophthalmic goiter. Star states that we may have a Basedow neurosis without the typical exophthalmic goiter ever developing. The syndrome of such a neurosis is given by Kraepelin as follows: cracking of the voice, tremor of the hands, poor judgment, illusions, hallucinations, mistrust or suspicion, groundless dislikes and jealousy.

Attempts to explain the occurrence of psychic disturbances in disease of the thyroid gland are based on a relationship between the activities of this gland and the central nervous system. Modern investigators believe that exophthalmic goiter is due to an increased activity of the thyroid (Moebius), to a perverted function (Gauthier), or to a combination of the two. It is not unreasonable to suppose that altered thyroid function would have some effect on the nervous tissues. Recently a connection between the thymus and the thyroid has been established in this disease, and during the time of its maximum development, the thymus seems of special importance to the nervous system. In instances of decreased thyroid activity, the hypertrophied or persistent thymus may act in a compensatory manner, and excessive activity on the part of this gland may be as dangerous as hyperactivity of the thyroid. Bainbridge[3] suggests that the mental changes are dependent on nutritional disturbances of the brain, the latter resulting from a perverted secretion or hypersecretion of these glands. Undoubtedly thyroid secretion influences the nutrition of the entire body, but too little is known of the interrelation of the secretions of the ductless glands to allow us to determine in what manner the nervous tissues are affected.

So far as is known, there has been no microscopic examination of brain tissues from patients with exophthalmic goiter and the Basedow psychosis. Ramadier and Marchand, however, have examined the thyroid glands of many insane patients to find if there was any connection between the psychic condition and the parenchyma of the gland. Among the cases studied were acute and chronic dementia, melancholia, dementia praecox, epilepsy, etc. Aside from considerable fluctuation in the weight of the gland, which is also true in normal individuals, there were no gross changes. Microscopically, numerous circumscribed, sclerotic foci or regions of interstitial inflammation were found, but glands from persons who have not suffered with mental or thyroid disease present similar changes. Further, these changes were present in nearly every instance of mental disease, and did not seem to depend on the type or severity of the malady. These investigators could find no relation between changes in the thyroid and mental disease, and conclude that toxins or other injurious substances which are able to affect the brain and cause mental disturbances may at the same time attack the thyroid.

The manner in which the so-called Basedow psychosis is affected by operation has been considered by Bainbridge, who states that surprisingly prompt effects are noted following thyroidectomy, and that a complete recovery may be reasonably expected in all but the severe forms of psychoses. In such cases it is unreasonable to hope that merely removing the causative factor will repair permanent damage already done the nervous centers.

Thus the rather large and varied group of nervous disturbances attendant on exophthalmic goiter may be classed under one head as the Basedow psychosis. The relation between the goiter and the psychosis is clear and well defined, but the factors which produce the mental changes and the structure alterations which occur are not definitely known.

ENDOWED MEDICAL SCHOOLS

Until the last decade, medical education seemed to have no attraction for the philanthropists. On the contrary, medical schools were considered not only as self-supporting but also as money-making institutions. It is noteworthy, however, that, as the colleges have changed in character during the rapid improvement in medical education in recent years, their financial needs have been met. Especially with the tremendous development of medical education during the past ten or twelve years, there has been a corresponding increase in the number of gifts for endowments, new buildings and support.

These gifts have been so generous for some institutions as to make them equal if not superior in resources to the leading medical schools abroad. Since, in 1906, Harvard Medical School secured its beautiful new buildings, the Peter Bent Brigham Hospital, the Huntington Cancer Hospital, the State Psychopathic and other hospitals have been built in the immediate vicinity and brought into close affiliation, resulting in the development of a great medical center. Johns Hopkins Medical School, with its modest start in 1896, has since been developed by large additions to its endowment, by the increased provision for medical research and the expansion of its hospital, until it, likewise, ranks among the world's great medical schools. There have been marked developments at Pennsylvania and Michigan and, more recently, at Minnesota and Tulane. New medical buildings at less expense but proportionally of equal importance, in recent years, have been erected for the medical schools of the Universities of Georgia, North Carolina and Nebraska and for the Medical College of South Carolina. A beautiful new medical library building has been secured for Leland Stanford, and greatly increased hospital connections, leading to the development of more compact medical teaching plants, have been obtained by Western Reserve University and the University of Cincinnati, as well as by Jefferson, Louisville and Iowa. Vanderbilt has emerged from a long struggle with adversity, has received a liberal endowment and is now undergoing a rapid growth.

---

[1] Paaron: Neurol. Zentralbl., 1913, No. 3.
[2] Colla: Allgemein. Ztschr. f. Psychiat., 1913, lxx, 525.
[3] Bainbridge: Med. Press, 1915, xcix, 86.

Because of the multiplicity and variety of these developments in medical schools, one is inclined to underestimate the importance and magnitude of the recent achievements at St. Louis. The dedication of the new buildings of Washington University Medical School marks the completion of another great medical teaching institution in the United States, of which the whole country may well be proud. With generous endowment, the Barnes and the St. Louis Children's hospitals and this high grade medical school have built splendid new buildings in immediate proximity, the total expense being over three million dollars. Of greater significance, however, is the fact that these institutions have formed a close affiliation by which they can work together to fulfil in the best manner possible a threefold function: (*a*) to furnish the best and most enlightened care of the sick in accordance with modern medical knowledge; (*b*) to add to the positive knowledge regarding the cause, cure and prevention of disease through scientific research, and (*c*) to furnish courses of instruction by which the public will be provided with thoroughly trained physicians and nurses.

In the light of all these remarkable achievements in medical education, it is not surprising that as great, or perhaps greater things are being planned in other parts of the country. These recent accomplishments, therefore, give confident expectation that the plans for a ten million dollar medical center at Columbia University will be successfully worked out. Surely, no development is more worthy of generous support; no investment could bring greater returns in the saving of lives, in the prevention of sickness and distress, and in promoting the welfare of the public.

BACTERIAL VARIATIONS

The question of variation, which has long attracted attention in connection with the biologic study of the most diverse forms of animal and plant life, has at length become a timely topic in bacteriology. The variability of micro-organisms in certain respects has, of course, been known since the days of Pasteur; for it was early realized that within the same species of bacteria, different races or strains may exhibit widely varying degrees of virulence. Such fluctuations have appeared to represent, to a large extent, degrees of adaptation on the part of bacteria to the conditions found in the living body. Not only, furthermore, can infectiousness be enhanced by the passage of micro-organisms through animals of certain species, but the virulence of bacteria can also be attenuated by laboratory manipulation.

The problem of variation in bacteria, however, is something more than one of alterations in the property of infectiousness which may or may not be a biologic attribute of relatively recent acquisition. Professor Jordan[1] of the Department of Hygiene and Bacteriology at the University of Chicago points out that in recent years some confusion has arisen through the difficulty of distinguishing true variations from the development of latent characteristics, and from environmental variation. There are qualities or properties which may be dormant in the organism or cell and are manifested only in response to definite external influences. This Jordan illustrates by the case of certain bacteria which form spores in the presence, but not in the absence, of oxygen. He very properly maintains that the sudden appearance in this way of a definite morphologic character cannot be looked on as an instance of true variation. Such a manifestation is merely an immediate response to changed conditions of life — it is the awakening of a dormant character. The importance of standardizing culture mediums lies in no small measure in the fact that latent qualities often play an important part in bacterial identification, and that it is sometimes impossible to recognize a given organism until it is brought into a peculiar environment and has given an appropriate response.

Although the great majority of bacterial variations that have been described belong to the class of apparently adaptive modifications, it now seems likely that true mutations occur. To fit this category they must fill the requirements of appearing suddenly without intermediate stages, of being irreversible, and of not involving all the cells of the parent strain. Jordan describes a bacterial mutation of this sort exemplified in the sudden acquisition of sucrose-fermenting powers by one of a pure line strain of *Bacillus coli.* Cultures of the parent organism grown in sucrose broth for a series of generations as yet have shown no gas or acid production. The particular mutation noted, therefore, seems to be due, in the words of Jordan, to the intracellular or molecular changes brought about by nonspecific influences and not to a direct adaptation to particular environmental conditions. All who are interested in questions of bacterial identification will appreciate the significance of such contentions. The distinction between an innate capability for certain types of reaction and a true fundamental mutation is not always easy to discover. In relation to the possible pathogenicity of organisms, this comparatively new domain of research calls for special critique and discriminating reserve of judgment. New micro-organisms are sometimes merely old ones in a new guise.

THE NOMENCLATURE OF DRUGS

The decision of the International Commission on Zoological Nomenclature in regard to the name "ancylostoma" has excited lively interest.[1] This seems somewhat singular in view of the general indifference to the nomenclature of drugs. Perhaps it would be better to say that the apathy of the medical profession toward the deplorably chaotic condition of drug nomenclature is singular and requires explanation. Certainly no irregularity and no innovation in the naming of a parasite can produce the harm and inconvenience that result from the haphazard naming of remedial agents.

The first requisite of successful prescribing is to know what one is giving. If the prescriber has not clearly in mind the exact properties and character of the drug prescribed, he does not know that drug. The mellifluous and meaningless name preferred for its "convenience" to a chemically descriptive name is too often an alias, masking the actual relationships of the substance. Thus, whereas the name "diacetylmorphin" tends to remind the user of the dangerous properties of the drug, the convenient name "heroin" has no such associations; undoubtedly the name has conduced to more reckless employment of this habit-forming preparation. The name "atoxyl" was given to sodium arsanilate presumably to indicate its alleged harmlessness; but the preparation has belied its name by exhibiting decidedly poisonous action. The influence of the name must have been both actively and passively mischievous — actively, so far as it seemed to promise innocuousness, and passively so far as it merely disguised the real nature of the drug.

Since the action of drugs depends on their chemical nature, the names should at least suggest the chemical composition and relationship of the substances (as the name "acetanilid," indicating a compound of acetic acid and anilin) or, at any rate, indicate from what they are derived (as the names "cocain" from coca, and "strophanthin" from strophanthus). The tendency toward names like antipyrin (against fever), diuretin (to promote the urinary flow) and migrainin (for headache)—that is, toward names suggestive of a therapeutic use rather than of the actual properties and character of the drugs—is one to be deplored and discouraged. Such monstrosities as "veronal" (said to commemorate the fact that one of the promoters of the drug thought of this name while passing through Verona) and "stovaine" (a pun on a man's name) are objectionable simply because they give no clue to the real character of the substance.

Then in the case of preparations protected only by trademarked names, the financial side comes in. Hexamethylenamin is quoted under this, its correct name, in a current catalogue at 13 cents an ounce; under the proprietary and therapeutically suggestive names "Uritone," "Urotropin" and "Cystogen," at 35 cents, 60 cents and $1 an ounce, respectively—certainly a high tax for a short name. Theobromin sodium salicylate was for years quoted under its true name at 35 cents an ounce; under the proprietary name "Diuretin," the same substance, not superior in any respect, is quoted at $1.75 an ounce—an increase of 400 per cent. in price for a name!

Why are arbitrary proprietary names accepted so readily, and correct scientific names rejected? Why do some physicians, for instance, stumble over "phenolphthalein," but readily remember the therapeutically suggestive proprietary name "Purgen"? The difference in the number of syllables is not the sole reason, for the five-syllabled name "acetanilid" has become so familiar that even laymen use it freely.

In the first place, the proprietary name is advertised and the scientific name is not. We have adopted the "catchy" names bestowed by manufacturers, not simply because they are short and therapeutically suggestive, but because they are kept before our eyes, forced on our consciousness and stamped on our memories by advertising.

In the second place, in the past every medical student was compelled to learn anatomy and pathology, and was thus enabled to understand the meaning of anatomic and pathologic terms, no matter how many syllables they contained, whereas chemistry and pharmacology were so slighted that most medical students had little, if any understanding, of the principles of chemical terminology. Such students (now physicians) find no difficulty in remembering the anatomic names "supinator radii brevis" because they understand what each component of the term means; but the U. S. P. name "hexa-methylen-amin," so thoroughly understood by the organic chemist, means nothing to them, and consequently they forget it readily. For this they may be pardoned; but they are less pardonable if they try to make their ignorance a reason against the general adoption of a scientific nomenclature. The younger members of the profession, moreover — those who have graduated from the better class of medical colleges within the last ten years — ought to feel that an admission that they do not understand such chemical terms is discreditable; it means that they have failed to profit as they should have profited from both their preliminary and their medical education. It is time for the profession generally to realize that an anatomy whose nomenclature depended on the inexact terminology of common speech would be no more discreditable and hampering to modern medicine than a pharmaceutical chemistry similarly bereft of scientific nomenclature. We should eschew the fanciful and therapeutically suggestive names provided by manufacturers. For nonpatented substances, let us use the U. S. P. or other nonproprietary names, and for new patented products, let us insist that names at least suggesting the chemical (not the alleged therapeutic) nature of the drug be adopted.

Current Comment

UREA IN HUMAN SPINAL FLUID

One of the criteria which have been offered as an indication of the genesis of special fluids in the body by a process of true secretion, that is, cell function, instead of mere transudation, is the existence of specific constituents in the product. Pepsin is ordinarily not found in the blood or the lymph; and similarly, other individual enzymes are confined to special secretions in the organism. The boundary lines respecting the distribution of enzymes are perhaps not so strictly drawn as they were a few years ago, but distinct limits of occurrence unquestionably exist. So in the case of other chemical substances, their appearance may be limited to a single fluid, as is that of the lactose of milk. The index of secretion is not limited, however, to the qualitative nature of the product. The dynamic factors of its production are also significant. Whether the cerebrospinal fluid is a true secretion or merely a modified tissue space fluid, or lymph, has not been conclusively determined on the basis of the foregoing principles. Some of the existing evidences have already been reviewed.[1] At one time the cerebrospinal fluid was looked on as unique in that it was supposed to be devoid of some of the soluble constituents characteristics of blood and lymph, notably sugar and some of the inorganic components. Little by little, with the increasing use of lumbar puncture, evidence has been furnished for the abundant presence of such substances for which the walls of the cerebrospinal spaces were once supposed to be impermeable. The latest to be added to the list is urea, the widespread distribution of which has been indicated before.[2] At the Hospital of the Rockefeller Institute for Medical Research, Cullen and Ellis have shown that when samples of human blood and spinal fluid are drawn within a few minutes of each other, the differences in the urea content of these two fluids is rarely greater than 2 milligrams per hundred cubic centimeters.[3] The greatest difference observed in thirty-two determinations on fifteen different patients was 11 mg. per hundred c.c. of fluid. The urea values varied from 20 to 42, and from 22 to 46 mg. of urea per hundred c.c. of serum and spinal fluid, respectively. These figures all lie within the possible range of normal variation. The occasional difference between the spinal fluid and the blood serum may be due to the rapid rise and fall of blood urea at different stages of protein digestion. From the nature of the processes of production of the spinal fluid, one might expect the changes in its urea content to lag somewhat behind those of the blood. As Cullen and Ellis remark, the results are in accordance with the already well-founded view[2] that the animal tissues are, in general, osmotically permeable to urea, which therefore tends to reach the same level of concentration in the different body fluids.

PELVIC MEASUREMENTS OF PHILIPPINE WOMEN

There is a traditional belief, supported by statements of scientific observers, that in childbirth among primitive peoples the mothers experience comparatively easy labor. An important, if not dominant factor in bringing about such a result must rest in anatomic conditions, and notably in the relationship in size between the pelvis of the mother and the head of the newly born infant. It has been asserted[4] that the pelvis of the females of less civilized races is narrower than that of the Caucasian race. A study of pelvimetry and cephalometry among Filipinas undertaken by Dr. Honoria Acosta-Sison[5] among patients in the obstetric wards of the Philippine General Hospital at Manila has furnished new data on this subject. It shows, by comparison with standard measurements made in the United States and elsewhere, that the diameters of the Filipino pelvis are shorter than those of the American or European pelvis. The relation of one diameter to another is altered in such a way that the proportion of the crests with the spines in the Filipino pelvis is much smaller than the proportion of the same diameters in the European or American pelvis, and that the proportion of the diagonal conjugate with the other diameters in the Filipino is very slightly larger than in the American. These facts, elicited by measurements of 117 cases, would seem to show that the Filipino pelvis is narrower and relatively deeper than the American pelvis. This diminution may be explained by the smaller stature of the Filipinas. More striking, however, is the observation that despite the smaller pelvis, the transverse diameter of the pelvic outlet in the Filipinas is the same as that of the Caucasian race. The relative enlargement of the outlet is explained by Acosta-Sison as the outcome of the habitual squatting position that the Filipino assumes, and by the fact that the custom of carrying of children astride the mother's or nurse's hip may also have an effect toward enlargement of the transverse diameter. The cephalic diameters of the Filipino children are smaller than those of Americans, and thus they are proportionate to and compensate for the smaller maternal pelvis.

AMERICAN SANITARY MISSIONARIES

A note from Dr. Samuel T. Darling, mailed at Gibraltar, announces his safe arrival to that point on his journey to Asia. It will be remembered that Dr. Darling was appointed as a member of the International Commission, Rockefeller Foundation, to investigate the cause of anemia in Malay. He has been connected for about ten years with the health administration in Panama — the work which set a standard for the world to follow. It is significant that the men connected with that work are being selected to act as missionaries in carrying to other parts of the world the efficiency of service there displayed. The work of Dr. Darling had already been recognized abroad by an honorary fellowship in the Society of Tropical Medicine and Hygiene of London, and a corresponding membership in the Société de Pathologie Exotique de France, the latter for his discovery of *Trypanosoma hippicum.* The discovery of this organism was followed by a complete investigation, which yielded a method of immunizing against this type of trypanosomiasis of mules, horses and other animals, and the knowledge that the disease was transmitted in corrals by the common house-fly. Dr. Darling accompanied Major-General Gorgas to the Rand and Rhodesia, and took part in the studies made there. The best wishes of his colleagues go with him to his new field of endeavor.

ONCE MORE A WARNING!

There is continually coming to this office evidence of the fact that doctors are still allowing themselves to be swindled by unauthorized solicitors under various representations. Evidence has been received that at least ten physicians have been victimized by these persons during the last six weeks. One active worker calling himself E. B. Huntington carries blanks bearing the name of the National Educational Association, 130 Nassau Street, New York City. As we have intimated before, there is no such association at that address. Two checks bearing the endorsement of this individual have been received this week. In one Huntington inserted his own name, making the check payable to him "or to the American Medical Association" — a pure case of forgery; in the other case the doctor apparently was inveigled into making the check payable to Huntington direct. In the latter case the doctor wrote "for the American Medical Association," evidently supposing that this would protect him. Huntington is not the only man who is traveling over the country working doctors and others. May we suggest that those who would avoid being swindled should not pay money to traveling men whom they do not personally know? Checks should not be made payable to any person, but to the concern the person claims to represent; and even then one should be very sure that there actually is such a concern. Money should not be paid to any one claiming to represent the American Medical Association unless he carries credentials bearing the signature of the Editor and General Manager and the seal of the Association.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Personal.—Dr. William P. Davidson, Sullivan, sustained a fracture of the clavicle by the overturning of his automobile near Danville, May 14.——Dr. Edmund A. Behrendt, Bloomington, who has been ill in St. Joseph's Hospital, is reported to be improving.——Dr. Isaac L. Beatty, Fairview, has been appointed an internal revenue collector and inspector under the Harrison law.——Dr. James A. Boyer, Carmi, injured his arm seriously while cranking his automobile, May 10.

State Medical Society Meeting.—At the sixty-fifth annual meeting of the Illinois State Medical Society held in Springfield, May 18 to 20, the following officers were elected: president, Dr. Charles W. Lillie, East St. Louis; president-elect, Dr. William L. Noble, Chicago; vice-presidents, Drs. Fred S. O'Hara, Springfield, and Henry P. Beirne, Quincy; secretary, Dr. Wilbur H. Gilmore, Mt. Vernon (reelected); and treasurer, Dr. Andrew J. Markley, Belvidere (reelected). The next annual meeting will be held in Champaign in May, 1916.

Lax State Health Laws.—After a three-months investigation of health conditions in Illinois by Surg. Samuel B. Grubbs, U. S. P. H. S., the Illinois State Board of Health, health laws of the state and the attitude of the people of Illinois toward the betterment of conditions are criticized severely. Recommendations are made that the State Department of Health should be reorganized by establishing the following divisions: communicable diseases, sanitation, vital statistics, publicity and education and examination, registration and accounts. The state, outside of Chicago, should be divided into at least eight districts with an inspector in each; a sanitary engineer should be named; births and deaths should be registered; the board should be notified of certain diseases, and vaccination should be required as a prerequisite to school attendance; occupational diseases should be studied; factories should be inspected, and communicable diseases should be placed under a stricter control. The practice of licensing itinerant medicine venders is vigorously condemned. The recommendation is made that the State Board of Health should be given supervision over the entire system of dairy inspections and, in conclusion, a vigorous campaign of sanitary education for the people of the state is urged.

Chicago

New Psychopathic Hospital.—Drs. Harold N. Moyer, Hugh T. Patrick and Sydney Kuh have been appointed a committee to investigate the new Psychopathic Hospital and to make recommendations for its utilization. The county board will then be asked to make the necessary appropriation for carrying on the work.

Play and Recreation.—On May 19 a special meeting of the City Club was devoted to a discussion of play and recreation in Chicago, and a special exhibit of Chicago's school parks and properties was held. Papers were read by the mayor, members of the park commission, principals of the schools, and several invited authorities on playground subjects.

Personal.—Dr. Wallace K. Harrison has been elected a director of the Western Unitarian Conference.——It is announced that Mayor Thompson has decided to retain Dr. Theodore B. Sachs at the head of the Municipal Tuberculosis Sanatorium.——Dr. and Mrs. Anders Doe celebrated their silver wedding anniversary May 17.——Dr. Julius Gottlieb is reported to be seriously ill with pneumonia.——Dr. Robert L. I. Smith has arrived in Bordeaux on the Steamer *Espagne*.——Dr. James W. Walker has been placed in charge of a military hospital in London and will sail for England in a few days.——Dr. R. C. Crumpton, for the past year connected with St. Luke's Hospital, has removed to Webster City, Iowa.

The Chicago Unit for Service Abroad.—The following physicians have already volunteered for service in the field hospital organization under the charge of Dr. James M. Neff, chief of staff: Drs. Philip S. Chancellor, Earl P. Ball, Robert B. Acker, Elbert L. Cavenee, Philip M. Dale, Joseph J. Hilton, R. B. Haven, A. H. Hixon, Frederick C. Jacobs, Daniel F. Hayes, John G. O'Malley, Charles A. Maghy, William A. McGuire, C. R. Stanley, S. Walker, George G. Davis, G. E. Meyer, and the following out-of-town physicians have volunteered, Drs. John S. Fox, Silverton, Colo.; Lee Edgar and Waldo Richardson, Seattle, Wash.; R. D. Long and J. K. McLean, Oklahoma City; C. S. Smith, Kalispell, Mont.; S. Terrall, Dallas, Tex.; J. R. Taylor, Madison, Wis.; W. J. Uppendahl, Peoria, Ill.; R. L. Thompson, St. Louis, and George P. Gill, Rockford. Headquarters of the Chicago unit have been established at rooms 237-238 Monadnock Building, and are open from 2 to 6 each day.

MARYLAND

Honor to Councilman.—A banquet was given May 13, by his former students and friends, in honor of Dr. William T. Councilman, formerly of the medical faculty of Johns Hopkins and now of Harvard Medical School. At the banquet a portrait of Professor Councilman was presented to him. The presentation address was made by Dr. Charles W. Mitchell, Baltimore, and Dr. William S. Thayer acted as toastmaster.

Special Medical Department Established.—Dr. Winford H. Smith, Baltimore, superintendent of Johns Hopkins Hospital, announces that a gift of $16,500, to be paid in three yearly installments, has been made by John D. Rockefeller, Jr., to be used for a special medical department at the hospital, to be established in September for the treatment of contagious diseases, with special reference to syphilis. The money is donated through the Rockefeller Bureau of Social Hygiene. The work of the clinic will be in charge of a committee consisting of Drs. George Walker, Theodore C. Janeway and Smith, and the dispensary will be in charge of Dr. Albert Keidel, Baltimore.

Personal.—Dr. Roscoe W. Hall has succeeded Dr. David K. Henderson as resident physician of the Phipps Clinic of Johns Hopkins Hospital. Dr. Henderson has been appointed superintendent of the Royal Asylum of Scotland, Glasgow, and will assume his new duties about June 1. He sailed for Glasgow May 15. Dr. Charles B. Thompson, Baltimore, has been appointed first assistant resident physician at the Phipps Clinic.——Dr. Walter L. Nicholls, Baltimore, underwent operation at Mercy Hospital, May 13, and is reported to be doing well.——Dr. Paul M. Stewart, U. S. P. H. S., has been assigned to take charge of the branch office in Baltimore during the absence of Surg. James A. Nydegger, Baltimore, who sailed for Europe recently to study medical conditions abroad.——Senior Surg. Henry R. Carter, superintendent of the United States Marine Hospital, Baltimore, and government sanitary expert, is recovering from a slight operation. He leaves shortly for the South where he will engage in sanitation work in the malaria districts of Alabama, Georgia and other Southern states for the next three months. During Dr. Carter's absence, Surg. Charles W. Vogel will be in charge of the hospital.

NEBRASKA

State Board Changes.—Governor Moorhead on May 20 appointed Dr. Lucien Stark, Hartington, secretary of the State Board of Health, succeeding Dr. Porter F. Dodson, Wilber, removed.

Correction.—In The Journal for May 22, it was announced that the state hospital building to be erected on the campus of College of Medicine of the University of Nebraska, Omaha, would cost with equipment, $50,000. The state legislature has appropriated $50,000 for the erection of the building and the equipment is not included in this sum. The hospital is to be a teaching hospital for the University of Nebraska, under the control of the board of regents, and is to receive indigent patients from the entire state.

State Association Meeting.—At the forty-seventh annual meeting of the Nebraska State Medical Association held in Hastings, May 18 to 20, under the presidency of Dr. John P. Gilligan, O'Neill, the following officers were elected: president, Dr. Edward W. Rowe, Lincoln; vice-presidents, Drs. Arthur C. Stokes, Omaha, and James V. Beghtol, Hastings; secretary, Dr. Joseph M. Aikin, Omaha (reelected); treasurer, Dr. Alexander S. von Mansfelde, Ashland (reelected); librarian, Dr. William P. Wherry, Omaha; delegates to the American Medical Association, Drs. Albert R. Mitchell and Artemas I. Mackinnon, Lincoln; alternates, Drs. Francis A. Long, Madison, and Burton W. Christie, Omaha; councilors, first district, Dr. B. Potts, Omaha; second district, Dr. Henry J. Lehnhoff, Lincoln; third district, Dr. Ira H. Dillon, Auburn; fourth district, Dr. Lucien Stark, Hartington; fifth district, Dr. Robert C. Byers, Nickerson; sixth district, Dr. John C. Malster, Stromsburg; seventh district, Dr. Wesley L. Curtis, Fairburg; eighth district, Dr. Patrick J. Flynn, O'Neill; ninth district, Dr. Miles S. Moore, Gothenburg; tenth district, Dr. Claude B. Calbreath, Hastings; eleventh district, Dr. Axel E. Hedlund, Dalton, and twelfth district, Dr. Alfred J. Stewart, Mitchell. The next meeting of the association will be held in Omaha.

NEW YORK

Tuberculosis Ward for Penitentiary.—In the Clifton prison there are said to be 407 convicts suffering from tuberculosis while there are only eighteen beds for tuberculosis patients. For this reason the governor has approved an appropriation for $75,000 for the erection of a general hospital containing a tuberculosis ward.

Reunion of University.—The fortieth annual reunion of the Alumni Association of the Medical Department of the University of Buffalo will be held in Buffalo June 1 to 4. On the first day there will be class reunions of the classes graduated five years and multiples of five years ago, and luncheons. On the second and third days, there will be scientific sessions and the annual business meeting. On Thursday evening, the alumni banquet will be held and on Friday morning, the graduating exercises will be held at the Teck Theater.

Fines for Quacks.—Of the 53 persons arrested several weeks ago in a campaign started by the district attorney, the police and the Medical Society of the County of New York against alleged fake medical museums, 23 were arraigned in special sessions on May 21. Six of the defendants were fined amounts ranging from $500 to $150. The others, who were merely employes, were released on suspended sentences. The defendants agreed to vacate the premises they had been occupying, not to advertise, to destroy exhibits in the museums, and not to permit unlicensed men to represent themselves as physicians.

Will Not Cut State Hospital Appropriations.—Governor Whitman announces that he will not veto the request for about $1,250,000 in the supply and construction bills of the state hospitals. Dr. William Mabon, superintendent of the Manhattan State Hospital and ex-state health commissioner, recently appeared before the governor and showed why this large appropriation was required. His data shows that the average overcrowding in the state hospitals is 22 per cent. and the overcrowding in the Manhattan State Hospital is 30 per cent. There are at present 1,400 more inmates than are provided for by the capacity of the buildings.

Rochester Has Clean-Up Week.—The Public Health Committee of the Rochester Chamber of Commerce had a "clean-up week," beginning May 16. Thirteen teams were appointed for the purpose of inspecting the city conditions, each team consisting of one member of the public health committee, one member of the fire prevention committee, and one uniformed fireman. A circular listing all known methods of getting rid of rats, mice, flies and mosquitoes was prepared by the committee. In addition, 15,000 clean-up "ticklers," indicating numerous specific localities that might profitably be inspected, were distributed in the schools and the children were asked to examine their own homes and surroundings and record the conditions that should be remedied and what they have done to improve them.

Vaccination Campaign.—Under the title "The Mutilated Vaccination Law" a writer in the *Bulletin* of the Health Department discusses the menace in the amendment of the vaccination law which does not make vaccination compulsory for school children excepting in cities of the first and second class, "unless smallpox exists in any other city or school district or in the vicinity thereof and the state commissioner of health shall certify in writing to the school authorities" that smallpox exists. Under this law the school children of the city will be protected in a fairly satisfactory degree, but the adult population with its immense quota of immigrants and visitors is by no means protected. A vigorous campaign for the protection of the adult population will be conducted.

New York City

Guarding Against Typhus.—Owing to the reported prevalence of typhus fever at Greek ports, eighty-two steerage passengers who arrived on the Steamer *Patris*, May 16, were held at quarantine for observation.

Arbuckle Memorial Building Opened.—The Arbuckle Memorial, completing the north wing of the Long Island College Hospital, Brooklyn, was opened May 24. The wing is five stories in height, 210 by 34 feet, and cost $250,000. It was presented to the hospital in memory of the late John Arbuckle by two of his sisters. The new building will house 171 male patients and, besides the wards and private rooms, it contains a clinical laboratory for 45 medical students and three research laboratories. The addition of this wing completes the physical plant of Long Island College Hospital, valued at two million dollars. The institution now has seven buildings devoted to the education of medical students and to the care of the sick, with accommodation for nearly 500 patients.

Personal.—The degree of Doctor of Laws was conferred on Dr. Simon Flexner by Johns Hopkins University on May 20.——Dr. Lucien P. Brown, state food and drug commissioner of Tennessee, has been appointed director of the bureau of food inspection in the Department of Health at a salary of $5,000 per annum.——Dr. and Mrs. George Paul have sailed for Liverpool on the *St. Paul*.——Dr. Robert T. Irvine, Ossining, was seriously injured by the overturning of his automobile near Ossining, May 15.——Dr. Benjamin Schwartz has been appointed to fill the vacancy in coroner's physicians caused by the resignation of Dr. Otto H. Schultze.——A dinner was tendered to Dr. A. L. Wolbarst on May 12 by the physicians who had attended his genito-urinary clinics at the West Side German Dispensary and Hospital, during the winter session.

NORTH DAKOTA

Hospital to Be Built.—The commissioners of Mercer County have accepted the proposition of the citizens of Hazen to erect a county hospital at that place to cost about $10,000. The citizens of Hazen will erect the building and install the heating and lighting plant, and the county will furnish and maintain the institution until it becomes self-supporting.

State Association Meeting.—At the twenty-eighth annual meeting of the North Dakota State Medical Association held in Bismarck, May 11 to 13, under the presidency of Dr. R. Hudson Beek, Lakota, [illegible] s were elected: president, Dr. Victor H. [illegible] vice-presidents, Drs. Victor J. LaRose, [illegible] M. Williamson, Grand Forks, and Edgar A. Pray, Valley City; secretary, Dr. Hezekiah J. Rowe, Casselton (reelected); treasurer, Dr. William F. Sihler, Devils Lake; councilors, Drs. Allan L. Nicholson, Max; William P. Baldwin, Casselton; Gustave Golseth, Jamestown, and Charles MacLachlan, New Rockford; delegate to American Medical Association, Dr. Charles S. Crane, Grand Forks; alternate, Dr. James P. Aylen, Fargo. The association recommended for the State Medical Examining Board, the names of Drs. Hugo O. Altnow, Mandan; B. Lyle Meigs, Edgerley, and Henry G. Woutat, Grand Forks. Devils Lake was selected as the next place of meeting.

PENNSYLVANIA

Jefferson Alumni Meeting.—More than seventy-five graduates of Jefferson Medical College and members of the southern chapter of the Jefferson Alumni Association met in York, May 13, and elected Dr. Martin L. Wolford, Harrisburg, president, and Dr. J. Harvey Miller, York, secretary-treasurer. Harrisburg was selected as the place for the all-day clinic and meeting next year.

Summer Course in Anatomy.—The department of anatomy of the school of medicine of the University of Pittsburgh, announces that it will give six summer courses in anatomy this year, from July 5 to August 28, inclusive. These courses are in gross anatomy; cytology, histology and splanchnology; hematology; embryology; neurology, and anatomy of the eye, ear, nose and throat.

Antivivisectionists Lose Again.—An attempt made in the house, May 18, to destroy the effect of the Gerberich bill, which allows vivisection of animals in the interests of science, was voted down, 75 to 50. The bill has passed the senate and is now on third reading in the house. The bill provides for the sale, distribution and use "for the promotion of biological science and for the discovery of new methods of treatment in medicine and surgery" of unclaimed animals in the public pounds. The amendment offered today provided that the bill should apply to animals "except dogs and cats." As this practically would have destroyed the purpose of the measure, it was voted down.

Personal.—Dr. Samuel A. Silk, for the last two and one-half years a member of the staff of the Pennsylvania State Sanatorium, Mt. Alto, has resigned to take up private practice in Sharon.——Dr. Robert Kilduffe, Jr., has been elected director of the pathological department of the Chester Hospital.——Dr. Henry J. Lacier, Bethlehem, underwent surgical operation at Johns Hopkins Hospital, May 6.——Dr. Charles H. Smith has been elected a member of the medical staff of the York Hospital.——Dr. Thomas C. Detwiler, Lancaster, sustained a comminuted fracture of the leg and other severe injuries by the overturning of his automobile near Lancaster, April 30.

Dixon Reappointed.—Dr. Samuel G. Dixon, Philadelphia, whose renomination as state commissioner of health was sent to the senate by the governor, May 17, was confirmed by that body, May 18. This is the third reappointment of Dr. Dixon to this responsible position and he has completed nearly ten years of valuable service to the commonwealth in this position. Under his direction the department of health has attained high rank among the public organizations of the country and its activities have reached all sections of the state. In the campaign against tuberculosis, 115 tuberculosis dispensaries have been established and three state sanatoriums have been constructed under Dr. Dixon's supervision. Since he assumed charge of the health department, the death rate from typhoid fever has decreased more than 75 per cent.

Philadelphia

Hospital Opened.—The new home of the Babies' Hospital of Philadelphia, Manoa Road near Llanerch, was formally opened May 15.

Rodman Honored.—The annual social evening of the West Branch of the Philadelphia County Medical Society was held at the Hotel Marlyn, May 17, and Dr. William L. Rodman was the guest of honor.

Personal.—Dr. Simon Wendcos has been elected a director of the Hebrew Literary Society.——Dr. William H. E. Wehner has been appointed medical director of the Fidelity Mutual Life Insurance Company, succeeding Dr. William H. King, resigned.

Municipal Courts New Clinic.—A clinic for inebriates has been introduced by the chief probation officer of the Domestic Relations Court, under which men addicted to drink and brought before the court or complained of by their wives, can undergo medical treatment. Dr. John Wanamaker, third city police surgeon, has volunteered his services.

Commencement.—The sixty-fifth anniversary and annual commencement exercises of the Woman's Medical College of Pennsylvania will be held Wednesday, June 2, at the Garrick Theater. The alumni conference of the college will be held June 4 and 5. Among the speakers at the commencement exercises will be Dr. Richard C. Cabot of Harvard University, the originator of social service work in connection with hospitals.

Philadelphia Contingent for Paris.—The Philadelphia contingent for service in the American Ambulance Hospital at Neuve will sail for Europe, June 12. Dr. J. William White will be executive head of the expedition; Dr. James P. Hutchinson, surgeon; Dr. Daniel J. McCarthy, neurologist; Drs. Edmund B. Piper, Walter Estell Lee, Arthur E. Billings and Peter McCall Keating, assistant surgeons, and Dr. Samuel Goldschmidt, bacteriologist. Four nurses will also accompany the party.

Doctors Volunteer for War.—The names of six physicians who have volunteered for the medical unit of thirty doctors now being raised by William Potter, former minister to Italy, for war medical service in France, have been made public. Those accepted are, Drs. John F. McCloskey, Frank C. Abbott, John A. Murray, Patton, Pa.; LeSieur Weir, Philadelphia; Edward L. Moore, Statesboro, Ga., and Alvin M. Struse, Roxborough. Dr. Charles E. de M. Sajous has made a conditional offer to join the unit, provided the situation between the United States and Germany does not become acute and war threaten.

Jewish Hospital's Semicentennial.—The fiftieth anniversary of the Jewish Hospital, which really occurred February 15 last, will be observed with impressive ceremonies on Memorial Day, when Governor Brumbaugh and other prominent men will take part in the exercises. Since the opening, fifty years ago, 33,248 patients have been treated in the hospital, 1,259 in the Lucien Moss Home, 3,300 in the Guggenheim annex, and nearly 164,000 in the dispensary. The cost of maintenance in 1865 was less than $5,000, while during the last year it was more than $149,000. In 1865 there was but one medical assistant, while at present there is a chief resident, with six assistants, and eighty-eight consulting physicians and surgeons.

Clean-Up Week.—So as to carry clean-up week into slum homes in the foreign section of the city, a group of women physicians from the Woman's Medical College has carried on an active campaign of sanitation, the out-patient department of the college being used for headquarters. The foreign settlement in the neighborhood was divided into sections to each of which a physician and one or more nurses was appointed. These started an energetic house-to-house canvass, urging the householders to clean and air their homes; disinfect sinks and drains and to clean up alleys and yards, etc. The committee in charge of this work consisted of Dr. Alice W. Tallant, chairman, and Drs. Theodore LeBoutillier, Ellen C. Potter, Leo H. Bernd, Katherine Radley, Helen H. Taylor and Jennie Severine.

CANADA

Health Inspector Killed.—Among the list of the killed in action, May 11, appears the name of Private Joseph H. Jones, formerly health inspector for the municipality of Assiniboia.

Public Hygiene Instruction.—The first class in public hygiene instruction under the direction of St. John's Ambulance Association was held May 10 in Saskatoon. Dr. John A. Valens was the lecturer of the evening.

Meeting Cancelled.—The annual meeting of the Canadian Association for the Prevention of Tuberculosis, which was to have been held in Vancouver at the same time as the Canadian Medical Association, has been cancelled until after the war.

Fraternity Cemented.—The council of the College of Physicians and Surgeons of Manitoba has been successful in its negotiations with Great Britain for reciprocity and now it is announced that graduates of the Manitoba Medical College may practice anywhere in the British dominions without further examination.

War Notes.—Capt. David Smith, M.D., Stratford, Ont., has been appointed to command the field hospital of the Thirty-Third and Thirty-Fourth Overseas Battalions at London Concentration Camp.——Vancouver, B. C., has offered to equip a general hospital of 1,040 beds for service abroad. It is to consist of 35 surgeons, 75 nurses and 200 men.——A Western contingent of the Canadian Army Medical Corps left Halifax, N. S., early in April. It comprised detachments from Victoria, Vancouver, Edmonton, Calgary and Winnipeg.——Dr. Neiley, New Glasgow, N. S., is serving with one of the hospitals in France.——Dr. Charles M. Burroughs, Sudbury, Ont., has enlisted for service in the Army Medical Corps.——Dr. Howard Ferguson, Toronto, is serving as surgeon on one of the English Channel transports.——Drs. Robert H. Smith, Wickware and William M. Brown, Moose Jaw, Sask., have received appointments in the Royal Army Medical Corps.——Dr. William R. Mason, Parry Sound, Ont., has volunteered for service with the St. John's Ambulance Corps in France.——Dr. Andrew Croll, Saskatoon, Sask., has left for hospital service, probably in Havre, France.——Major David A. Clark, Toronto, was among the wounded at Langemarck.——The divisional officers of the second Canadian contingent have been named. Lieut.-Col. John Taylor Fotheringham, Toronto, is named assistant director of medical services, and Major Jacques, Ottawa, deputy assistant director of medical services.——Dr. Herbert A. Bruce, Toronto, tendered a goodby reception to the Toronto University Base Hospital on the afternoon of May 13. Lieutenant-Colonel Roberts was present with his staff, and some eighty nurses. The hospital required $30,000 for equipment. They obtained some $80,000, the Fulford estate, Brockville, Ont., contributing $40,000. In addition a woman of Cleveland, Ohio, donated a handsome limousine for convalescent soldiers.——Lambton County (Ont.) medical men offer to furnish a general hospital of 200 beds for the use of the Canadian militia in France.

Personal.—Dr. Reginald de Lothbiniere-Harwood, Edmonton, Alta., has been gazetted lieutenant-colonel and placed in command of the Fifty-First Battalion and has volunteered for overseas service.——Dr. Angus W. McPherson, medical officer of health of Peterboro, who left to join the army medical service May 10, was presented on the evening before with a silver tea service on behalf of the various civic bodies of Peterboro.——Dr. F. F. Wesbrook, president of the University of British Columbia, was entertained in Minneapolis, May 8, while on his way from the East to Vancouver.——Dr. Alexander Fisher, Calgary, Alta., has been appointed superintendent of the Calgary hospitals.——On April 30, Drs. J. J. Field and Warren A. Dakin, Regina, who have been appointed to the Royal Army Medical Corps, were given a banquet by the medical fraternity of the city.——Dr. H. V. Robinson, for three and one-half years a member of the medical staff of the Protestant Hospital for the Insane, Verdun, Que., resigned to accept a position in Montreal.——Dr. Darius A. Coon, Elgin, Ont., has been appointed superintendent of the General Hospital, Kingston, Ont., in succession to Dr. Harry A. Boyce, resigned.——Dr. John P. Sinclair has been appointed medical officer of health of Gananoque, Ont.——Dr. John W. S. McCullough, chief medical officer of Ontario, has been appointed assistant sanitary expert to the International Waterways Commission.——Dr. John D. Courtnay, Ottawa, has been appointed a special member of the Canadian medical force at the front to look after wounds and diseases affecting the eyes, ears, noses and throats of soldiers.——During the absence abroad of the editor, Dr. Andrew Macphail, Montreal, and the general secretary, Dr. William W. Francis, Montreal, the Canadian Medical Association and its *Journal* will be conducted by Drs. George Gordon Campbell and John W. Scane, Montreal. The former for many years edited the *Montreal Medical Journal*, and the latter is registrar of the medical department of McGill University.——President Falconer of the University of Toronto and Prof. Irving Howard Cameron deny that the latter has tendered his resignation. Mr. Cameron has announced that after his long service, he is contemplating resigning.——Dr. John L. Chabot, M. P., for the city of Ottawa, was a passenger on the torpedoed *Lusitania*, and so far no report has been received of his survival.——Major Thomas Bedford Richardson, Toronto, who has recovered from a prolonged illness dating from September last, has taken up his military duties and has been placed in charge of the hospital at Exhibition Camp, Toronto.——Dr. W. J. Gibson, Belleville, Ont., is said to be seriously ill.——Dr. William Gunn, Clinton, Ont., has gone on a trip to the Panama-Pacific Exposition.

GENERAL

Climatologists to Meet.—The American Climatological and Clinical Association will hold its thirty-second annual meeting in San Francisco, June 18 and 19, under the presidency of Dr. Henry Sewall, Denver.

Federation Moves.—The Scientific Temperance Federation announces the removal of its headquarters and library and also the editorial department of the *Scientific Temperance Journal*, to 36 Bromfield Street, Boston, Mass.

Tuberculosis Foes to Meet in Seattle.—The annual meeting of the National Association for the Study and Prevention of Tuberculosis will be held in Seattle, June 14 to 16. Thus far, twenty-one states and the province of British Columbia have signified their intention of sending delegates.

Mid-West Specialists Hold Meeting.—The Mid-West Academy of Ophthalmology and Oto-Laryngology held its first semi-annual meeting in Joplin, Mo., May 24, under the presidency of Dr. John D. Pifer, Joplin. President and Mrs. Pifer entertained the members at dinner in the evening of May 24.

American Gastro-Enterological Association.—At the executive session, the following officers were elected for the ensuing year: president, Dr. Charles G. Stockton, Buffalo; first vice-president, Dr. William J. Mayo, Rochester, Minn.; second vice-president, Dr. Ludwig W. Kast, New York City; secretary and treasurer, Dr. Franklin W. White, Boston.

New Officers for Neurologists.—At the annual meeting of the American Neurological Association held in New York City, May 13 to 15, the following officers were elected: president, Dr. Llewellys F. Barker, Baltimore; vice-presidents, Drs. Herman H. Hoppe, Cincinnati, and John J. Thomas, Boston, and secretary-treasurer, Dr. Alfred Reginald Allen, Philadelphia.

Immunologists Hold Meeting.—The second annual meeting of the American Association of Immunologists was held in the New Willard Hotel, May 10, and the following officers were elected: president, Dr. James W. Jobling, Nashville, Tenn.; vice-president, Dr. George P. Sanborn, Boston; secretary, Dr. Martin J. Synnott, Montclair, N. J.; and councilor, Dr. John A. Kolmer, Philadelphia.

Medical Milk Commissions to Meet.—The ninth annual conference of the American Association of Medical Milk Commissions will be held in San Francisco, June 17 to 19, under the presidency of Dr. Thomas C. McCleave, Berkeley, Cal. The headquarters will be at the Hotel Bellevue and the sessions will be held in the Municipal Auditorium, San Francisco, and the University of California, Berkeley.

Examination of Dentists for Army.—The Surgeon-General of the Army announces that examinations for the appointment of twelve acting dental surgeons will be held at Fort Slocum, N. Y.; Columbus Barracks, Ohio; Jefferson Barracks, Mo.; Fort Logan, Colo, and Fort McDowell, Calif., Oct. 18, 1915. Before October 4, application blanks and full information can be procured by addressing the "Surgeon-General, U. S. Army, Washington, D. C."

Canal Zone Personal.—Dr. Alfred G. Farmer, Gatun, who has been in the service of the Panama Canal since August, 1905, has resigned, to take effect May 31, and will return with his family to the United States. Dr. Farmer has served in both the Ancon and Colon hospitals, as district physician at Corozal and Gatun, and during the last year has been chief of the medical service of the Colon Hospital.——Dr. Edward P. Beverly has reentered the Canal service and has been assigned to duty as chief of the medical service of the Colon Hospital.

Southern Sociologists Hold Meeting.—At the annual meeting of the Southern Sociologic Congress in Houston, May 10, Dr. Oscar Dowling, New Orleans, was elected first vice-president, and Dr. J. W. Dillard, Lynchburg, Va., a member of the executive committee; and the following committee on medical profession and health was selected: chairman, Dr. Watson S. Rankin, Sanatorium, N. C.; secretary, Dr. Lewis B. McBrayer, Asheville, N. C.; and Dr. Powhatan S. Schenck, Norfolk, Va.; Surgeon Rudolph H. Von Ezdorf, U. S. P. H. S., New Orleans; Dr. Khleber H. Beall, Fort Worth, Tex.; Dr. Charles W. Garrison, Little Rock, Ark., and Miss Mary Gearing, Austin, Tex.

Medico-Psychological Association Annual Election.—The seventy-first annual meeting of the American Medico-Psychological Association was held in Old Point Comfort, Va., May 11 and 12, under the presidency of Dr. Samuel E. Smith, East Haven, Ind. The following officers were elected: president, Dr. Edward N. Brush, Towson, Md.; vice-president, Dr. Charles G. Wagner, Binghamton, N. Y.; secretary-treasurer, Dr. Henry C. Eyman, Massillon, Ohio, and executive council, Drs. Samuel E. Smith, East Haven, Ind.; Charles P. Bancroft, Concord, N. H.; Arthur P. Herring, Baltimore, and James M. Forster, Toronto, Ont. New Orleans was selected as the next place of meeting.

Internists Elect Officers.—The annual meeting of the Association of American Physicians was held in Washington, D. C., May 11 to 13, and the following officers were elected: president, Dr. Henry Sewall, Denver, Colo.; vice-president, Dr. George Dock, St. Louis; secretary, Dr. George M. Kober, Washington, D. C.; recorder, Dr. Thomas McRae; treasurer, Dr. J. P. Crozer Griffith, Philadelphia; member of the executive committee of the Congress of American Physicians and Surgeons, Dr. Theodore C. Janeway, Baltimore; and alternate representative, Dr. Richard P. Strong, Boston. The thirtieth anniversary dinner of the Association was held May 12, at which Dr. George M. Kober presided.

Pennsylvania Optometry Bill Vetoed.—The Pennsylvania Legislature recently passed a bill providing for a separate board of examiners for "optometrists" which Governor Brumbough promptly vetoed. In his veto message the governor said: "This board is created in a way that is contrary to all precedent. To limit the executive in his appointments to a professional body to whom is entrusted the conservation of human vision by compelling and directing him to appoint only those selected by the executive committee of a society that has no obligation or responsibility to the people, and a society whose members are in no legal way related to the people at large is contrary to the policy of law. Only members of said society would be eligible to place on the board, notwithstanding the fact that there may now be and in the future there may arise other societies whose functions it is or may be with equal competence to administer to the human eye. In the formation of other state boards the executive is not so limited and no reason has been given me why this limitation should be made. The judgment and the discretion of the executive cannot be delegated to legally irresponsible bodies. This restriction is fundamentally wrong.

"There is no convincing reason why those practitioners should not voluntarily place themselves under the existing licensing body of the commonwealth. . . . The standards of professional service in this commonwealth are and have been high. We are a center of professional services of the most commendable standards. These standards must be safeguarded and exalted. No official act of the commonwealth should in any way lessen the standards of admission to a professional career in this commonwealth nor the standards of professional training to fit for technical service. The human eye is priceless. The care and treatment is a sacred service. The sanction of the state, which is the sanction of the people, cannot be lightly bestowed."

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Luke's Hospital, New York City, $3,000 for a bed for the use of Grace Church, by the will of Miss Adelaide Hamilton.

St. Francis' and St. Mark's hospitals, New York City, each $500 by the will of Xavier Steultzle.

American Theatrical Hospital, Chicago, $7,000, the proceeds of a benefit performance, May 9.

Harvard Medical School, $10,000 for the endowment of a scholarship; Instructive District Nurses Association, Boston, $24,000, to support a nurse under the direction of the Boston Lying-In Hospital by the will of Fannie Bartlett, Boston.

Seton Hospital for Consumptives, New York City, $26,787, Service for the Relief of Incurable Cancer; St. Agnes' Hospital and Misercordia Hospital, each $5,000 by the will of Catherine Reilly, New York City.

Presbyterian Hospital, New York City, one-half of the residuary estate of $137,244, on the death of his wife, by the will of Frederic Baker, New York.

Hospital of the Protestant Episcopal Church, Philadelphia, $10,000; Pennsylvania Hospital, $5,000; Protestant Episcopal Home for Consumptives, $5,000; Christ's Church Hospital, Philadelphia, $10,000, on the death of her sister-in-law, by the will of Sally Robert Smith.

University Hospital, Philadelphia, $5,000, for the endowment of a free bed to be known as the Dr. John Neill bed in memory of her father, by the will of Patty D. Neill.

Home for Crippled Children, $2,000, by the will of Emma Paul.

St. Louis University School of Medicine, the estate of James Campbell, valued at from $6,000,000 to $10,000,000, subject to the life tenure of his wife and daughter.

Miami Valley and St. Elizabeth's hospitals, Dayton, Ohio, each $5,000, for the establishment of free clinics for those suffering from ailments of the eye, ear, nose and throat, by the will of Mrs. Mary B. Greene.

Johns Hopkins Hospital, Baltimore, $16,500, for the establishment of a new department for the treatment of contagious diseases, donation from John D. Rockefeller, Jr.

Presbyterian Hospital, Manhattan, $20,000; St. Vincent's Hospital, Manhattan, $10,000; Hospital Guild of the New York Medical Hospital and College, Manhattan, $10,000; Bellevue Hospital, Manhattan, $10,000; New York Ophthalmic Institute, Manhattan, by the will of William Washington Cole.

Miami Valley Hospital, Dayton, Ohio, $1,000, by the will of Dr. Colby.

Indiana University, Bloomington, a donation of $100,000, to be used in scientific research, from Dr. Luther D. Waterman, Indianapolis.

FOREIGN

Place de Curie.—The name of Curie, in honor of the discoverer of radium, has been given to a small park formed by the tearing down of the old rue Dauphine in Paris.

Edinger's Sixtieth Birthday.—A number of German and foreign neurologic journals dedicated their current issue to Professor Edinger of Frankfurt in honor of his sixtieth birthday, April 13. Several articles, also, in nonspecialist medical journals are being dedicated to him.

Vaccination Required of Matriculants.—Some of the universities and colleges in Austria are now requiring of applicants a certificate of vaccination since Jan. 1, 1910. Up to May 3 there had been 1,173 cases of smallpox in Vienna since the beginning of the war, with 252 deaths.

Reappearance of More French Exchanges.—The *Archives des Maladies du Coeur*, the *Journal d'Urologie*, and *Annales de Gynécologie et d'Obstétrique* have resumed publication, each saying that the missing numbers for 1914 will be made up in the course of the current year to complete the volume to which the subscribers are entitled.

Maternity Hospitals for Cuba.—The president of Cuba has signed a law providing $400,000 for the erection of six maternity hospitals, one in each province of the island. Of this sum, $100,000 is alloted for the hospital in the province of Habana, and $60,000 each for the hospitals in the other provinces. The money is to be appropriated from the sum accruing to the state from unclaimed lottery prizes.

Campaign Against Alcohol in Austria.—The Austrian *Permanenz-Komitee* for industry, trade and commerce has recently petitioned the government to interfere to check liquor drinking. The petition states that it is unwise to leave the restriction in the hands of local authorities and political interests. The state should take the matter in hand. Among the measures proposed are that the sale of whiskey and brandy should be limited to the hours between 7 and 12 in the morning, and 2 and 3 in the afternoon, and none be sold on Sunday and holidays nor to persons under 16 at any time, nor to persons known to be habitual drunkards. The petition urges strict enforcement of these measures, and the closing of saloons for repeated infractions, also a penalty for persons found drunk in public places, and for saloon keepers selling to those already drunk. The government, while appreciating the necessity for stricter measures against alcohol, is of the opinion that the matter should be left to the local authorities to handle, as they can conform the regulations to local conditions.

WAR NOTES

More Nurses for Austria.—The American Red Cross sent nine additional trained nurses to Austria, via Genoa, Italy, on the steamer *Duca d'Aosta*.

Captives of War in Germany.—According to an official statement, there were up to April 15, 812,803 prisoners of war in Germany. Before any of the Russian captives are detailed for work on farms they are carefully examined for trachoma, etc.

Anonymous Gifts to Red Cross.—The second anonymous gift of $10,000 to the war relief fund of the American Red Cross was announced May 20. The first gift was reported from Philadelphia and the second donation from Massachusetts.

Sheets, Pillow Cases and Towels Needed.—Mr. H. O. Beatty, director-general of the American Relief Clearing House, Paris, writing under date of May 6, states that there is a great need for cotton sheets, pillow cases and towels in connection with war relief work in France.

Exposition of Arrangements for Caring for the Wounded.—Budapest is having an exposition showing the organized care for the wounded and sick in the war and for hygiene and sanitation in general at the front. It is similar to the exhibition recently held at Berlin, and Germany has sent a special exhibit.

Danish Field Hospital in France.—An exchange states that Professors Ehlers is in charge of the Danish hospital unit recently installed in one of the French cities near the seat of war. Tscherning, surgeon in chief of the public hospital of Copenhagen, and two other surgeons, are with him. The unit is planned for twenty-four beds.

Exchange of Severely Wounded Prisoners.—The *Medizinische Klinik* states that 200 severely wounded French soldiers have already reached Constance, ready to be exchanged for severely wounded German soldiers, captured by the French. This is the first consignment of 1,200 wounded prisoners whom the Germans are collecting for exchange.

High Cost of Drugs in Austria.—The wholesale dealers in drugs in Austria have raised their prices by 10 per cent., while the price of the raw materials has gone soaring to 400 per cent. and more. The associated pharmacists are complaining to the authorities that foreign specialties from the enemies' countries are being smuggled into the country.

Reenforcement for Sanitary Commission.—In response to an appeal from Dr. Richard P. Strong, Boston, for further assistance in Serbia to battle with typhus and other epidemic diseases, twenty-seven additional sanitarians sailed for Serbia, May 10, on the steamer *Athinai* for the Piraeus. A large quantity of medical and sanitary supplies was also sent by this steamer.

Appreciation from German Red Cross.—A letter from the president of the German Red Cross, dated in Berlin, April 15, acknowledges the aid of the American people and its appreciation therefor. The letter also acknowledges receipt of four carloads of gifts from the United States and of the ambulances donated by the students of Yale and Harvard universities.

Thanks from Austria.—The American Red Cross has received a letter from Count Traun, president of the Austrian Red Cross, acknowledging the receipt of a shipment of wearing apparel, linen and hospital supplies sent by the *Finland* via Genoa, and also of the four motor ambulances donated by the students of Harvard and Yale universities, which were shipped by the *Cretic*. Two motor ambulances and one-half of the consignment of hospital supplies were forwarded to the Hungarian Red Cross.

Medical Practice at Rome in Case of War.—The Surgical Association of the Province of Rome has joined in the organized arrangements for civilian medical practice throughout the province. All in the arrangement have agreed to assume the practice on request of the members of the profession called to the colors, and to pay to the families of the colleagues they are substituting all the fees received minus a certain small percentage to be determined by the vote of the officers of the association.

Austrian Society to Combat Epidemic Diseases.—An association of medical and laymen has been founded at Vienna to disseminate information among the public as to the nature of epidemic diseases and means of warding them off. The officers include Profs. von Pirquet and O. Stoerk. One of the first measures to be undertaken is to send a mission to Turkey to aid in combating epidemic diseases there, as an important measure to save Austria from invading plagues. A leading merchant is getting up the expedition, assisted by other nonmedical men.

Appalling Conditions in Serbia.—Dr. Richard P. Strong, Boston, chief of the American Sanitary Commission sent to Serbia by the American Red Cross, Rockefeller Foundation and Serbian Relief Committee, to study epidemic diseases, cables that he has just returned from a second inspection trip, that typhus and recurrent fevers are prevalent among all classes, that at Monastir seven physicians are ill with typhus fever, that in many places there are no doctors at all and that although the conditions are very appalling, the work is progressing satisfactorily. A supplementary party of twenty-six sanitary experts and a large quantity of sanitary and medical supplies was sent to Serbia, May 16, on the steamer *Athinai*.

New Quarantine Hospital in Bohemia.—The largest military hospital on the continent is said by the *Wiener klinische Wochenschrift* to be almost completed at Pardubitz. All the wounded and sick soldiers reaching Bohemia have to spend a few days in this hospital, which will have 10,000 beds to begin with. There are 206 pavilions and 125 administration buildings, with railroad station, postoffice, etc. The personnel is to consist of 125 physicians and 750 nurses. The bacteriologic department is in charge of Professor Jedlicka of Prague. There are provisions also for barracks for soldiers. The sick and wounded reaching Bohemia are kept under observation here for a few days and are then transferred to the "clean" part or to one of the pavilions for contagious diseases, as the case develops. It is hoped in this way to keep epidemic diseases out of the country.

Aid for Belgian Physicians.—The following is an extract from a letter from Dr. George W. Crile of Cleveland:

> "When I was in Belgium I received first-hand information from a number of Belgian physicians concerning their plight. They are indeed in dire need and there seems to be no way by which this need can be overcome until their land is restored to them again. The free masonry of the medical profession so binds all medical men together that it seems to me that no appeal to doctors for the aid of their associates in Belgium can be in vain. We should all realize also that no single appeal can satisfy what is going to be a long continued need, that we must give now, later again, and still later and so answer repeated appeals until later conditions may restore to the Belgians the wherewithal to aid themselves."

The report of the treasurer of the committee of American Physicians for the aid of the Belgian profession, for the week ending May 22, 1915, lists the following contributions:

Dr. H. M. Manning, P. A. Surg., U.S.P.H.S., Charleston, S. C.		$ 5.00
Anonymous—K., Toledo, Ohio		5.00
Dr. Dwight G. Kreul, Davenport, Iowa		10.00
M. L. H., Wallum Lake, R. I.		3.00
Knox County Medical Society, *Fredericktown*, Ohio		10.00
The Medical Club of Portland, Portland, Ore.		25.00
Dr. Edward E. Bancroft, Wellesley, Mass.		10.00
Dr. Thomas St. Clair, Latrobe, Pa.		5.00
Dr. Fred T. Murphy, St. Louis Mo.		50.00
Dr. Hermann Grad, New York, N. Y.		10.00
Receipts for the week ending May 22		$ 133.00
Previously reported receipts		6,860.50
Total receipts		$6,993.50
Disbursements for the week ending May 22:		
178 standard boxes of food at $2.28	$ 405.84	
Previously reported disbursements:		
1,625 standard boxes of food at $2.20	$3,575.00	
1,309 standard boxes of food at 2.30	3,010.70	
Total disbursements		6,991.54
Balance		$ 1.96

F. F. Simpson, M.D., Treasurer,
5 Jenkins Arcade Building.

PARIS LETTER

Paris, May 6, 1915.

The War

THE DISCHARGE OF TUBERCULOUS SOLDIERS

Professor Landouzy, dean of the Faculté de médecine de Paris, recently presented to the permanent commission on tuberculosis of the interior department a report on this subject which is rendered very opportune by the war. He first takes up the army statistics showing temporary and final discharges for tuberculosis. The number is considerable already and is sure to be greatly increased by the present concentration of troops. Landouzy believes that the years 1915 and 1916 are going to send out over the country 20,000 tuberculous subjects to scatter the germs of the disease in the regions in which they settle after their discharge. This regrettable state of affairs could be modified by radical measures on the part of the war department. It is indispensable in the first place to eliminate without hesitation every man who is affected with open and hence dangerous tuberculosis. In the next place, tuberculosis should not be, as at present, the disease in which is most seldom applied the form of discharge which permits a temporary or permanent pension. It is believed, to be sure, that tuberculosis is rarely contracted in barracks and that military life is seldom the source of infection. This may be true, but the overexertion inseparable from this life is without doubt the greatest factor in causing the latent disease to become active. Men who contract or develop tuberculosis under such conditions readily become sources of infection in their turn; they are eligible for the form of discharge just mentioned. Today the danger is increased by the fact that the *conseils de revision* have just placed in active service men who were previously discharged because of tuberculosis but who are now found in good condition and may again become a source of danger owing to the uncomfortable life of the trenches and promiscuity which it entails. When these men become unmistakably tuberculous and incapable of taking part in the campaign, as they too frequently do, has the army the right simply to rid itself of them by discharging them and taking no further interest in them? How about those whom these tuberculous patients infect? Landouzy believes that, on the contrary, the army should, to a certain extent and for a limited time, assume the responsibility for such invalids. This would tend to encourage a more rigorous selection at all stages of the service. Men discharged on account of tuberculosis ought not to leave the army without being assured of treatment, education in regard to tuberculosis and assistance. Such measures would tend to protect the general population from carriers of the disease. After this war there will be tuberculous patients who will be war invalids just as much as are the soldiers wounded in battle. The nation owes the same debt of gratitude to both. This debt is all the more sacred so far as the tuberculous patient is concerned because his disease has, to some extent, set him apart as a source of danger to the rest of the population.

THE WAR AND DECEPTIVE ADVERTISEMENTS

I mentioned in a previous letter (The Journal, Oct. 3, 1914, p. 1217) how certain unscrupulous manufacturers in advertising their goods have brazenly imitated the official notices to the public on the subject of hygiene. M. Edmond Bonjean, member of the Conseil supérieur d'hygiène publique de France, has just made a very detailed report to the Société de médecine publique, in regard to deceptive advertisements on subjects of public hygiene. He shows that certain preparations promoted by ingenious publicity and recommended as a sure means of avoiding epidemics are entirely without efficacy. Such advertising may have an injurious effect on the public health, for it leads those who put faith in it to neglect really effective methods, such as immunizing vaccinations or rational disinfections. In a period of national emotion, during a unanimous outburst of patriotism and generosity, says Bonjean, such misleading advertisements easily induce the public to buy these ineffective specialties and send them to the soldiers. Bonjean believes that the law for the repression of frauds might be applied to these dangerous misrepresentations.

AUTOMOBILE SURGICAL AMBULANCE

One of the aims most diligently sought by the military medical service has always been to be able to give soldiers wounded at the front the necessary surgical attention as soon as possible. The first aid posts and the first line ambulances unfortunately cannot perform major surgical operations under satisfactory conditions and the wounded are compelled to be removed to base line hospitals before being operated on; often, therefore, the operation is made too late. Automobile surgical ambulances constitute a great advance in this respect. A real flying surgical hospital, capable of being installed near the front, in which it is possible to operate on a great number of the wounded, can thus be realized. The installation comprises nine 20 horse power automobiles. Six serve for the transportation of the supplies and the staff, one is a radiologic laboratory, another carries the autoclave and the last is the pharmacy. The head surgeon chooses a situation by the side of an ambulance in which he can place his patients after operation. The cars immediately take the places appointed for them. In half an hour a tent is pitched and a surgical pavilion installed. It includes three apartments; a preparation room, a dressing room and an operating room with four tables. The autoclave car is placed at a right angle to the side of the operating room so as to open into it. In front is the radiologic car provided with the latest improvements and permitting precise investigations. The whole is lighted up with electricity furnished by the motors and floored with sheets of aluminum. Everything is capable of being cleansed by having water turned on. The whole constitutes a complete surgical installation which might be envied by many permanently housed institutions. A hundred wounded men can be cared for there during a day. The staff consists of a head surgeon, six assistants, a pharmacist, an administrative officer and twenty-five nurses, of whom ten are medical students. The first of these mobile formations set out for the front May 5. The construction of thirty others is under way.

AID FOR MEN BLINDED IN THE WAR

Devoted teachers are instructing those poor soldiers who have become blind in the ingenious Braille method of writing and reading. The books in Braille characters, however, are very expensive, for the process of printing them is a lengthy and delicate one, and this has limited the output.

A cultivated young blind man has just founded an association the members of which pay a modest annual fee, the sum thus obtained being used to print in Braille characters good books of every kind. As a fitting token of gratitude, the association has been given the name of the Swiss oculist and friend of the blind, Dr. Marc Dufour. Among its active and honorary members the Association Marc Dufour numbers the surgeon C. Roux, Professor Combe and Dr. O. Dufour; it has already an income of about $200 a year. Requests for further information, applications for membership, gifts, etc., may be addressed to the Association Marc Dufour, Chez M. E. G. Carey, avenue Agassiz, 3, Lausanne, Switzerland.

Death of Professor Thoinot

Dr. Léon-Henri Thoinot, professor of legal medicine at the Faculté de médecine de Paris, has just died suddenly of hemorrhage, aged 57. In 1906 he succeeded his master, Professor Brouardel, in the chair of legal medicine. He was a physician of the Laennec Hospital and since the outbreak of the war had been head of the contagious disease service at the military hospital of Val-de-Grâce. His studies had been especially on the subjects of hygiene, sanitation and disinfection. He had made numerous investigations on epidemics of typhoid in miliary fever and diphtheria. He was highly esteemed as an expert in judicial circles.

BERLIN LETTER

Berlin, April 20, 1915.

Death of Löffler

April 9, the professor of bacteriology, Frederick Löffler, died at the age of 62. Immediately after the outbreak of the war he departed to the battle front and served as advisory hygienist to one of the army corps, performing his duties with great earnestness. In November, following an attack of severe intestinal trouble, he was compelled to return home. An operation was deemed necessary, and Professor Bier discovered the presence of a pancreatic carcinoma.

Löffler was born June 24, 1852, at Frankfurt-on-the-Oder, where his father, who subsequently was director of the Pépinière in Berlin and a distinguished military surgeon, was serving as regimental surgeon. After a short period of study in Wurzburg, Löffler entered the Pépinière, which is today the Kaiser-Wilhelms Academy, and after his graduation became a military surgeon in Hannover. Later he served in the same capacity in Potsdam, and in 1879 was appointed to the state sanitary department, working chiefly in the chemical and hygienic laboratory under Sell and Wolffhügel. In 1880, when Robert Koch was appointed director of the national health department, he asked Löffler to enter his laboratory and Löffler had a large share in Koch's work on infection and sanitation. Löffler studied particularly questions of immunity. In 1881 he discovered a mouse bacillus against which, after several injections, he was able to immunize rabbits. After much study on the causes of nasal infections, he discovered the diphtheria bacillus, and for this work he obtained a world-wide reputation.

In 1884 he left this service and became a member of the staff of the Kaiser-Wilhelms Academy, where he continued his investigations. He was then offered the position of director of the chemical hygienic laboratory in the state military service. After he was established as a teacher in hygiene, in 1886, he was called as professor to Giessen and Greifswald in 1888. He decided on the latter university, where he worked until 1913, when he was called to succeed Gaffky as director of the Robert Koch Institute for Infectious Diseases in Berlin. In Greifswald, Löffler devoted himself chiefly to the infectious diseases of animals, and discovered various facts concerning methods of prevention of epidemics. He worked on the prevention of foot and mouth disease, and outlined a method of immunization, which was tested on some animals on a small island in Greifswald Bay, in order to prevent a wider dissemination of the disease. Up to the time of his death, Löffler worked to make his method less costly, as the high price of the immunizing serum prevented its general adoption. Löffler also discovered the causes of the red murrain of pigs and other hog diseases.

Löffler's name is one which is today known throughout the world for his scientific discoveries, of which those mentioned form but a small part.

Congress of Military Surgeons in Brussels

At the suggestion of the chiefs of the field hospitals, a congress of the German military surgeons was held at Brussels in place of the meeting of the German Surgical Society usually held in Berlin; about 1,200 surgeons assembled from all the battlefields, April 1, 1915. Papers were read by prominent surgeons, but for sundry reasons their discussion had to be omitted.

TREATMENT OF HEMORRHAGE

The first paper by Generalarzt Garrè was on the handling of hemorrhage both at the front and later. The stopping of bleeding is one of the most important tasks of the field surgeon. When only the usual tampons and constrictors are used, there may still be enough bleeding from some vessels to result in death. Garrè recommended as the most accurate method of controlling hemorrhage the clamping of bleeders with forceps that are left in place until the dressing is changed. He also spoke of the use of transfusion with physiologic salt solution in cases in which the loss of blood had been great, and stated that stimulus by camphor, caffein, etc., was often more efficacious in impending cardiac failure. Early operation was also advised for skull injuries and for abdominal wounds in which there was danger of internal hemorrhage or injury to stomach or intestines. The earlier the operation in these cases, the better is the prognosis. The necessity for early relief under unfavorable conditions of wounds of the lower urinary apparatus makes the use of the methods used in time of peace impossible and resort to bladder puncture necessary. Every bullet wound is at first, in all probability, not infected, but every grenade wound is; 83 per cent. of all Garrè's especially severe wound infections were due to grenades. This is natural when one considers that these bombs burst on the ground and so carry into the wound dirt as well as fragments of infected clothing. Garrè believes that all such wounds should be thoroughly explored and cleaned out with the gloved hand in the field hospital (the advisability of this is questioned by other speakers). In wounds of the extremity, the speaker preferred conservative handling to early operation.

Generaloberarzt Friedrich of Königsberg spoke of his medical experiences and of the terrible condition of affairs that is arising on the Eastern Russian battle front. He also recommended the clamping of bleeders in preference to the use of constriction and tampons.

TREATMENT OF TETANUS AND GAS GANGRENE

The treatment of tetanus and gas bacillus infections was discussed by Generalarzt Kümmel of Hamburg. In the Crimean War, tetanus occurred in 1.5 per cent. of cases; in the American Civil War, in 2.5 per cent.; in the Franco-Prussian, in 3.5 per cent., and in the present war in 6.5 per cent. of cases. This shows how thoroughly the French soil is impregnated with the organism causing this disease. The early recognition of this disease is of greatest importance as it is much more difficult to cure when it is fully developed. Here again, and for the reasons mentioned above, the grenade wounds are the most dangerous. The sooner after the injury the symptoms appear, the worse is the prognosis in spite of the tetanus antitoxin. A combination of antitoxin with salvarsan has been advised, but Kümmel believes that magnesium sulphate is of greater value; the use of narcotics and the continuous water bath must also be considered. The speaker and many other observers recommend the use of a prophylactic dose of antitoxin, especially as little as 20 units will almost certainly suffice to ward off the disease. A most serious infection for which there is a specific cause is the gas bacillus infection. Its rapid course makes early energetic treatment necessary. A patient who is suspected of having such an infection should be carefully examined every two hours, and as soon as the diagnosis is established, the part must be radically opened up; a small incision in the skin and superficial fascia does not suffice, free incision down into the muscles being necessary. According to the work of Professor Franz, toxins are present in the blood even when there is no bacteremia.

TREATMENT OF SKULL INJURIES

Generalarzt Tilmann of Cologne spoke on skull injuries. In scarcely any type of wound is so great a variety of symptoms found as in skull injuries. While penetrating wounds of the skull often result in an early death, glancing wounds are almost as dangerous because of the more extensive injury to the brain that may be present. In penetrating wounds, the damaged brain tissue, etc., comes out of the larger wound of exit of the bullet; how much the brain is damaged depends on whether a fragment of bone is driven into it and on whether any vital centers are injured. The paralyses, etc., that are often present at first may disappear in a few days. When the wounds are first examined in the field where facilities for aseptic operating are not present, conservative treatment is advised; here only the stopping of hemorrhage and the removal of splinters of bone must be considered. Piercing wounds are operated on only after the bullet has been located by means of roentgenography. In diagnosing a meningitis, which often shows itself on the first day, a spinal puncture is often of great assistance. A more frequent form of infection following skull wounds is encephalitis, only the serous form of which is curable. Brain abscess is a condition both difficult to diagnose and to treat.

TREATMENT OF CHEST WOUNDS

That chest wounds are not so dangerous as might be expected has been clearly shown in the countless cases in the present war. Many cases of bullet wounds of the lungs not complicated by injury to the ribs or the larger pulmonary vessels heal rapidly. Bleeding into the pleural cavity from small arteries is, as Oberstabsarzt Sauerbruch of Zurich pointed out, rather a rare occurrence, and little blood is generally lost in this way. Much the most serious wounds are those produced by grenades. In summing up these cases, delayed hemorrhage and the rise in temperature due to secondary infection must be considered. The germs that escape into the pleural cavity with the injury to the lung find in the clotted blood an excellent culture medium. Simple drainage of the pleural cavity is generally all that is necessary in these cases, though at times it is necessary to operate on the lung itself. Those wounded through the lungs must be kept absolutely quiet. Generaloberarzt Borchard of Posen pointed out that a prolonged compression of the lung may be dangerous, especially when it is accompanied by thickening; when this is feared, after a suitable interval he makes an incision to permit the escape of the fluid and so relieve the lung.

TREATMENT OF PENETRATING WOUNDS OF THE ABDOMEN

In his discussion on penetrating wounds of the abdomen, Generalarzt Körte of Berlin cited many cases. He demonstrated that in this line of work the methods used in times of peace were not practicable, because such wounds are encountered rarely in time of peace and because of the complications presenting themselves in time of war, and on account of the difficulty of transportation. The prognosis in those cases which come up for treatment more than twelve hours after being wounded is bad. When the battle line is in motion, this delay in getting the wounded to a place where they can be cared for is more apt to happen than when the troops are intrenched and have their regularly appointed field hospitals in which it is possible to perform complicated operations. In spite of the great penetrating power of the bullets, piercing of the abdomen without injury to the intestines is rare, though it does occur. In a large series of penetrating wounds of the abdomen, Körte had a mortality of 60 per cent., which would have been even larger if the patients who did not live to get to the rear had been included. Internal hemorrhage and the almost certain injury to the viscera make early surgical treatment the safest method.

Oberstabsarzt Schmieden of Halle stated that the expectant treatment of these cases was all right in theory, but was not possible in time of war, as the necessary conditions such as absolute quiet could not be obtained in time of war. He took the stand that every patient with abdominal injury coming to the skilled surgeon less than twelve hours after being injured should be operated on at once; thus the exact nature of the damage may be ascertained, and if only the liver is injured, the hemorrhage may be stopped, or if the other viscera are injured, whatever is needed may be done. Also experience shows that while the percentage of cases of injury to the stomach or intestines is small, it is even smaller if operation is not performed early. Furthermore, the late complications of pregnancy, such as abscess, etc., which are often hard to diagnose, make the mortality even higher. He also stated the mortality was lower in those soldiers who, being in a dangerous place, were on short rations, had an empty gastro-intestinal canal and so were better prepared for intestinal wounds. Generaloberarzt Friedrich of Königsberg believed that wounds of the small intestine are more dangerous than those of the stomach, large intestine or liver. Generalarzt Rehn of Frankfort-on-the-Main made the same observation.

WOUNDS OF THE EXTREMITIES

Generalarzt Payr of Leipzig and Stabsarzt Goldammer treated the voluminous subject of wounds of the extremities. The great economic significance of this class of wounds makes it necessary to treat them with the greatest care. Here again grenade wounds are found to be the most severe, shrapnel next and bullet wounds least. With grenade wounds, free incision with complete removal of all dirt and pieces of clothing, splinters of bone, etc., is necessary. In spite of this, there is nearly always more or less infection which sometimes gives rise to a septicemia and sometimes to osteomyelitis. In all cases, a very firm dressing is contraindicated, and immobilization is of greatest importance, especially in joint wounds. This keeps the limb quiet and permits the best drainage of the wound. The speaker stated that plaster casts were of value, especially in cases that could not be under constant observation. The use of manufactured splints is possible only in hospitals, in which they are found very convenient, as Professors Rehn, von Eiselsberg and others said.

Marinegeneralarzt Bier of Berlin spoke on the surgery of blood vessels and aneurysms.

The establishment of numerous Roentgen-ray outfits was decided on at the meeting.

Personal

Prof. Carl Fraenkel has resigned his position as chief of the Institute of Hygiene at Halle, on account of his health. On the occasion of his baptism a few years ago (undoubtedly to favor the prospects of his son, an officer in the army), he changed his name to Fraenken. He had a cerebral hemorrhage ten years ago, although he was only 42 years old at the time. He recuperated completely from that attack, so that he was able to resume his teaching and research work. Fraenkel was one of Robert Koch's most gifted pupils, and has accomplished much in various fields of bacteriology and hygiene.

The seventieh birthday of Prof. Friedrich Merkel, director of the Institute of Anatomy at Göttingen, was celebrated April 5. He followed the anatomist Henle in this position in 1885. Among the manuals he has published, the best known are his revision of Henle's "Grundriss der Anatomie" and the "Handbuch der topographischen Anatomie."

The director of the Institute of Pharmacology at Halle, Professor Harnack, died April 24. Like his brother, the theologist of Berlin, he was born at Dorpat in Russia. He studied under Schmiedeberg, the Strassburg pharmacologist, and was called to Halle in 1889 as regular professor. He published a revision of Buchheim's manual of materia medica, the "Lehrbuch der Arzneimittellehre," and wrote for physicians a work embracing the principal facts of chemistry, "Haupttatsachen der Chemie," and has done research work in various fields of his specialty. He conducted a campaign against homeopathy, his articles appearing in the *Deutsche medizinische Wochenschrift*.

Professor Roentgen of Munich reached his seventieth milestone March 27, and to honor the occasion the kaiser presented him with the iron cross. The message of congratulations sent him by the kaiser at the same time said: "The German nation cannot be grateful enough to the discoverer of the rays for whom they are named. The many advantages from the use of the rays are being rendered apparent by the war more than ever before"—*Die segensreiche Verwendung der Strahlen lässt sie gerade jetzt im Kriege ausserordentlich schätzen.*

LONDON LETTER

London, May 14, 1915.

Death of Sir William Gowers

Sir William Gowers, M.D., F.R.C.P., F.R.S., the neurologist, has died at his residence in London. He had a brilliant career as a student, and graduated with the degree of M.D. from the University of London, in 1870, with a gold medal. At an early period he interested himself in nervous diseases, and was appointed to the famous Hospital for the Paralysed and Epileptic, Queen's Square, which may be considered the home of British neurology. He formed one of the brilliant galaxy which included Hughlings Jackson, Ferrier and Bastian, who were the founders of neurology in this country. In 1879 he delivered the Goulstonian Lectures and took for his subject epilepsy, to which his contribution was epoch making. He published a book on "The Diagnosis of Diseases of the Spinal Cord," which at once became a classic. For the first time he showed the intimate relation between the anatomy and the symptomatology of disease of the spinal cord. In 1885 appeared his "Diagnosis of Disease of the Brain." The clinical and pathologic observations of Hughlings Jackson and the experimental work of Fritsch, Hitzig and Ferrier had completely altered the conceptions of cerebral physiology and functions, and Gower's acute mind readily grasped the significance of their observations. He laid down principles and rules which at the present day are perhaps a little extended but scarcely in any way altered. Finally appeared his crowning work, the "Manual of Diseases of the Nervous System." His clinics were attended by physicians from all over the world interested in neurology, and he was considered easily the greatest diagnostician of the day in diseases of the nervous system.

Sickness Benefit Claims Under the Insurance Act

As pointed out in previous letters to The Journal, the insurance act has shown in the working several defects due to its socialistic nature. A committee appointed by the government has issued a report on the question whether the claims made on the funds, either of societies in general or of societies of particular types, are in excess of the claims which under a proper system of administration should have been made on and allowed by them. The committee finds little, if any, evidence of fraud on the part of insured persons, or of deliberate malingering, but considerable evidence of a tendency to take the utmost advantage of the benefits under the act. Taking women, as a whole, experience shows that sufficient provision has not been made for sickness benefit granted to them; that is, either the amount paid as premium is insufficient or the amount of the policy money is too great, and this applies both to single and to married women. In the case of both sexes great difficulty is caused by a doubt as to the meaning of the criterion of incapacity set up under the act, and the committee recommends that the conditions of sickness benefit should be more precisely defined. A new benefit is recommended to be paid to a pregnant woman, in respect to the last four weeks of pregnancy, whether she is incapacitated or not. It is also recommended that payment should be made to a pregnant woman who is incapacitated from following her occupation in the month previous to the last month, whether she is incapacitated by pregnancy alone or by pregnancy accompanied by some other condition.

The War

THE EVACUATION OF THE WOUNDED

An account of the exact method of dealing with the wounded may be of interest. The medical organization in the field consists at the front of two kinds of formations, those of "armies" and those of "divisions." The former are under a director of medical services who, while responsible for the working of all units and branches of the medical service within his army, has under his direct control the large clearing stations established within easy reach of the railway, the motor ambulance convoys, and all sanitary arrangements in the particular army area. The divisional formations are under the assistant director of medical services of the division, who controls the field ambulances, dressing stations, aid posts and sanitary sections in the divisional area. Take the case of a man struck by a bullet while advancing, and left lying in the open under a hail of shrapnel bullets, which are striking the ground all round. From this hazardous position he is rescued by two stretcher bearers who, choosing their moment, rush across, pick him up and carry him back to the shelter of a trench. These bearers may either be from his own unit, sixteen men of which, in the case of an infantry battalion, have been trained in the first aid and stretcher drill, or they may be men of the Army Medical Corps belonging to a bearer subdivision of a field ambulance. They will take him to his "regimental aid post," probably situated in a dug-out, in a cellar, or in some sheltered spot giving cover from fire, where he will receive first aid from the army surgeon attached to the battalion. From this he will be conveyed either on a stretcher or, if circumstances permit and a road is handy, in a horsed ambulance wagon to the nearest dressing station.

As soon as he is placed in the ambulance wagon, he passes out of regimental care into the charge of one of the formations of a division known as "divisional field ambulances." Such an ambulance is composed of three sections, each consisting of a bearer subdivision and a tent subdivision. The former are organized for the purpose of collecting the wounded, while the latter form dressing stations. The advanced dressing stations are pushed forward as close as possible to the front, and are situated in houses alongside roads so as to facilitate conveyance to and fro. On the arrival of the patient at one of these, his wound is carefully attended to, and he is injected with antitetanic serum. He is then carried by a motor or horsed wagon belonging to a divisional field ambulance to one of the larger dressing stations, which has been opened possibly in a school, a convent or a church in some town or large village situated further to the rear, where he is given food. Here the wounded are sorted according to the nature of their injuries, and prepared for transport to the casualty clearing station on motor ambulance wagons. They thus pass out of the hands of the division into the formations under direct control of the army.

The casualty clearing stations are generally situated at the railheads, so that patients can be carried direct from them to the ambulance trains. They are not hospitals in the true sense of the word; but a proportion of serious cases, such as those of certain kinds of injury to the head or abdomen, which cannot be moved without danger, may be retained in them for a considerable time. Equipped and staffed to deal normally with 200 patients, they have a sufficiently elastic organization to be able if necessary to cope with much larger numbers during the progress of a battle, and special arrangements are made for temporarily augmenting the staff when severe pressure is expected. Here the patient will for the first time experience the luxury of being tended by nursing sisters and of lying on a bed. The length of his stay will depend on the railway facilities; but as a rule it will not be more than a few hours before he is placed on an ambulance train. Once on board the train, he leaves what is known as the "collecting zone," and enters the "evacuating zone," and at the same time passes out of the charge of the medical authorities of the army into that of the line of communications.

On arrival at a base, the wounded man is again carried in a motor ambulance wagon to a fully equipped permanent hospital. These hospitals are of two kinds, general and stationary, the difference being chiefly in the number of patients accommodated. A third category of hospitals found at the bases is composed of Red Cross or voluntary hospitals. The personnel and equipment of these are provided by the society or subscribers who organized the unit; but each is under the command of an officer of the Army Medical Corps. A great difficulty experienced is that of reconciling the need of seriously wounded men for complete rest with the necessity for avoiding the congestion which would be caused by retaining them at the casualty clearing stations during an action, a time when large numbers of wounded have to be dealt with. Not many can be retained, and yet any movement or jolting such as that caused by a train or motor journey might involve grave risk. A solution of this problem has been found to a limited extent in the use of water transport on the excellent system of canals with which Northern France is supplied. The serious cases of this nature are carried by barge from the clearing stations near the front to the most advanced hospitals on the lines of communication. The barges have been specially converted into hospital craft, having been fitted with operating tables and all the necessary accessories, and each can accommodate forty patients. They are towed by tugs.

Marriages

Francis J. Townsend, M.D., to Miss Anna Rayne, both of Ocean City, Md., at Snow Hill, Md., May 4.

Hugo Oliver Peterson, M.D., to Miss Marie Euphrosyne Dahlstrom, both of Worcester, Mass., May 19.

William French Smith, M.D., to Miss Margaret R. Dawson, both of Somerville, Mass., May 12.

Louis Charles Deane, M.D., to Miss Mabel Short, both of San Francisco, at Los Angeles, May 9.

Clarence H. Bryan, M.D., to Mrs. Ray N. Mathews, both of Chicago, May 15.

Deaths

Nathaniel Eugene Wordin, M.D. Jefferson Medical College, 1875; a member of the Connecticut State Medical Society, American Academy of Medicine and American Public Health Association; for seven years secretary, and in 1905 president of that organization; once president of the Fairfield County and Bridgeport Medical associations; a member of the State Board of Health, from 1890 to 1899; for many years physician to the Bridgeport Hospital and Bridgeport Protestant Orphan Asylum; a veteran of the Civil War; well known as an author and historian; died at his home in Bridgeport, May 10, from cerebral hemorrhage, aged 70.

George Ansley Wilcox, M.D. New York University, New York City, 1871; a Fellow of the American Medical Association and a member of the Southern Medical Association; professor of gynecology in the University of Georgia, Augusta, and formerly professor of materia medica and therapeutics and of obstetrics in the same institution; gynecologist to the Augusta (Ga.) City and Lamar hospitals; one of the most prominent and beloved practitioners of Augusta, and the first to be given the honorary degree of M.D. by the University of Georgia; died at his home in Augusta, May 5, aged 64.

George Cornelius Bailey, M.D. New York University, New York City, 1886; a member of the Connecticut State Medical Society; for many years a member of the board of directors, consulting physician, head of the gynecologic department and president of the staff of St. Francis' Hospital, Hartford, Conn.; a member of the board of school visitors since 1896; died at his home in Hartford, May 10, from pneumonia, aged 50.

James Jackson Purman, M.D. Howard University, Washington, D. C., 1880; a veteran of the Civil War, who was awarded the Congressional Medal of Honor for gallantry on the battlefield of Gettysburg; formerly an attorney of Green County, Pa.; medical director of the Department of the Potomac, G. A. R.; since 1881 a clerk in the pension office; died at his home in Washington, May 10, aged 73.

Samuel G. Kelly, M.D. Northwestern University Medical School, Chicago, 1903; a Fellow of the American Medical Association and American Academy of Ophthalmology and Oto-Laryngology; and eye, ear, nose and throat surgeon for the Missouri, Kansas and Texas Railroad; died at his home in Sedalia, Mo., April 24, from cerebral hemorrhage, aged 34.

Jessie Wheeler, M.D. Womans' Medical College of Pennsylvania, Philadelphia, 1902; formerly a Fellow of the American Medical Association; a member of the Kansas Medical Society; formerly of Sacramento, Cal., but for the last nine years a practitioner of Salina, Kan.; died in St. Barnabas' Hospital, Salina, from malignant disease, aged 40.

Thomas Joseph McLoughlin, M.D. College of Physicians and Surgeons in the City of New York, 1869; a Fellow of the American Medical Association; surgeon to the Jersey City Hospital, and medical director of St. Francis' Hospital, Jersey City; died at his home in Jersey City, May 12, from septic pneumonia, aged 70.

Niles Harrison Shearer, M.D. University of Maryland, Baltimore, 1866; a member of the Medical Society of the State of Pennsylvania and American Academy of Medicine; surgeon of volunteers during the Civil War; a druggist and financier of York, Pa.; died at his home in that city, May 5, aged 73.

John Lloyd Brown, M.D. University of Louisville, Ky., 1885; formerly president of the Menifee County (Ky.) Board of Health, county referee and local surgeon of the Chesapeake and Ohio Railway at Morehead, Ky.; died at his home in Rothwell, Ky., April 13, from cerebral hemorrhage, aged 51.

Edward Clinton Fish, M.D. University of Michigan, Ann Arbor, 1883; a member of the State Medical Society of Wisconsin; for thirty years a practitioner of Mosinee, Wis.; and for twenty-five years justice of the peace; died at his home in Mosinee, May 9, from tubercular meningitis, aged 56.

Nelson G. West, M.D. Jefferson Medical College, 1854; a member of the Medical Society of Virginia and president of the Loudoun County Medical Society; surgeon in the Confederate service during the Civil War; died at his home in Leesburg, Va., May 11, from senile debility, aged 83.

James R. Willis, M.D. Long Island College Hospital, Brooklyn, 1876; formerly secretary of the Vigo County Board of Health and twice coroner of Vigo County, Ind.; once president of the Vigo County Medical Society; died at his home in Terre Haute, Ind., May 4, aged 61.

Jacob R. Brown (license, Indiana, 1897), for more than sixty years a resident of St. Joseph County, Ind.; surgeon of the Twenty-Ninth Indiana Volunteer Infantry during the Civil War; died at the home of his nephew in Crumstown, Ind., May 1, from senile debility, aged 91.

George Nelson Perry, M.D. Howard University, Washington, D. C., 1884; professor of obstetrics and pediatrics in his alma mater; a member of the Medical Society of the District of Columbia; died at his home in Washington, May 10, from heart disease, aged 64.

Charles Edward Fraser, M.D. Bellevue Hospital Medical College, 1871; once superintendent of the State Custodial Asylum, Rome, N. Y., and for two years coroner of Oneida County; died at his home in Lacona, N. Y., May 10, from cerebral hemorrhage, aged 65.

Ollie L. Townsend, M.D. Hospital College of Medicine, Louisville, 1881; a member of the Kentucky State Medical Association and president of the Farmers' Bank of Glensboro, Ky.; died at his home in Lawrenceburg, May 11, from disease of the spleen, aged 55.

Josiah Thomas Scovell, M.D. Rush Medical College, 1867; for ten years professor of science in the Indiana State Normal School and later head of the science department of the Wiley High School, Terre Haute, Ind.; died at his home in that city, May 8, aged 73.

Albert Joseph Roberts, M.D. Harvard Medical School, 1902; a member of the Connecticut State Medical Society; a member of the staff of the Bridgeport (Conn.) Hospital; died in that institution, May 11, from cerebral hemorrhage, aged 40.

Samuel Mardis Hogan, M.D. University of Louisville, Ky., 1873; a member of the Medical Association of the State of Alabama, and the Southern Surgical and Gynecological Association; died at his home in Montgomery, Ala., May 7, aged 77.

William B. Denny, M.D. Meharry Medical College, Nashville, Tenn., 1880; a well-known colored practitioner of Nashville; pastor of the Salem A. M. E. Church; died at his home in Nashville, May 4, from cerebral hemorrhage, aged 63.

Hugh R. Rutledge, M.D. Medical College of the State of South Carolina, Charleston, 1846; a surgeon in the Mexican War; and said to have been the oldest practitioner in Mississippi; died at his home in Greenville, May 6, aged 91.

Henry B. Roberts, M.D. Atlanta (Ga.) Medical College, 1882; representative from Crisp County in the Georgia Legislature and chairman of the County Board of Education; died at his home in Cordele, May 8, from nephritis, aged 63.

Thomas Perkins Smith, M.D. Harvard Medical School, 1880; a Fellow of the American Medical Association; formerly physician of the city and township of Westbrook, Maine; died at his home in Westbrook, May 7, aged 62.

Maximilian Jacoby, M.D. Long Island College Hospital, Brooklyn, 1910; of Chrome, N. J.; died in the Elizabeth (N. J.) General Hospital, April 9, from septicemia, due to Roentgen-ray burns of the finger, aged 32.

John Henry Urich, M.D. Boston University, 1892; assistant in the department of diseases of the skin and later lecturer on diseases of the skin in his alma mater; died at his home in Boston, February 26, aged 53.

James R. Glover (license, years of practice, West Virginia, 1881), formerly of Pennsboro, W. Va.; but for the last year a resident of Cleveland; died at his home in the latter city, March 11, from pneumonia, aged 70.

Horace Morgan Fritz, M.D. Jefferson Medical College, 1879; a member of the Medical Society of the State of Pennsylvania; died at his home in Quincy, May 12, from cerebral hemorrhage, aged 60.

Robert Augustus Stewart, M.D. New York University, New York City, 1878; formerly a member of the town council of Phillipsburg, N. J.; died at his home in that city, May 14, from heart disease, aged 64.

Sherman Edwards, M.D. Rush Medical College, 1893; for fifteen years a practitioner of Oakfield, Wis.; died in his apartments in Milwaukee, Wis., May 2, from tuberculosis, aged 50.

William F. Goldin, M.D. Atlanta (Ga.) Medical College, 1877; formerly representative and state senator from Haralson County, Ga.; died at his home in Draketown, Ga., May 10, aged 65.

Frederick Ira Beard, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1861; one of the oldest practitioners of Clark County, Mo.; died at his home in Kahoka, May 4, aged 74.

Isaac Newton Houston, M.D. Jefferson Medical College, 1880; a member of the West Virginia State Medical Association; died at his home in Moundsville, W. Va., May 3, aged 64.

Franklin Ellis Kelly, M.D. Louisville Medical College, 1895; a member of the Illinois State Medical Society; also a druggist; died at his home in Green Valley, Ill., April 29, aged 59.

James J. Reilly, M.D. University of Minnesota, Minneapolis, 1886; of Milton, N. Dak.; died in the state penitentiary, Bismarck, N. Dak., May 9, from pneumonia, aged 49.

Albert Felix Fuchs, M.D. Rush Medical College, 1882; a physician and druggist of Loyal, Wis.; died at his home in that place, May 5, from disease of the kidney, aged 58.

Jasemin McAlpin, M.D. Woman's Medical College, Baltimore, 1887; of Warren, Pa.; died in the Bradford (Pa.) Hospital, May 11, from intestinal obstruction, aged 50.

John Alphonsus Lee, M.D. College of Physicians and Surgeons, Boston, 1914; of Boston; died in the Framingham (Mass.) Hospital, May 6, from heart disease, aged 28.

Tirey C. Dollens (licensed, Indiana, 1897), formerly a member of the Indiana State Medical Association; died at his home in Trinity Springs, Ind., May 5, aged 71.

William Becker (license Md.); a veteran of the Civil War; and a practitioner since 1869; died at his home in Baltimore, April 25, from pneumonia, aged 70.

James B. Maple, M.D. Missouri Medical College, St. Louis, 1878; a veteran of the Civil War; died at his home in Custar, S. Dak., recently, aged 79.

Charles Neil Shellenberger, M.D. Pulte Medical College, Cincinnati, 1878; died in Colorado Springs, Colo., his home, April 29, from heart disease, aged 58.

John N. Frank, M.D. Washington University, St. Louis, 1869; twice coroner of St. Louis County, Mo.; died at his home in St. Louis, May 3, aged 66.

Thomas Stewart Blake, M.D. Medical College of the State of South Carolina, Charleston, 1849; died at his home in Ninety-Six, S. C., May 4, aged 88.

Samuel Thomas Cubbage, M.D. Jefferson Medical College, 1895; died at his home in Felton, Del., April 1, from pernicious anemia, aged 50.

John Fenton Kinney, M.D. Indiana Eclectic Medical College, Indianapolis, 1882; died at his home in Idaho, O., April 27, aged 63.

Silas W. Darrow, M.D. Homeopathic Hospital College, Cleveland, 1877; died at his home in Brockport, N.Y., May 5, aged 68.

Frederick W. Montgomery, M.D. Druidic University of Maine, Lewiston, 1882; died at his home in Wichita, Kan., May 4, aged 58.

Florestano Bruno, M.D. Chicago College of Medicine and Surgery, 1913; died at his home in Lawrence, Mass., May 1, aged 33.

E. L. Jacobs (license, Ark., 1903); died at the home of his daughter in Harrisburg, Ark., May 2, aged 82.

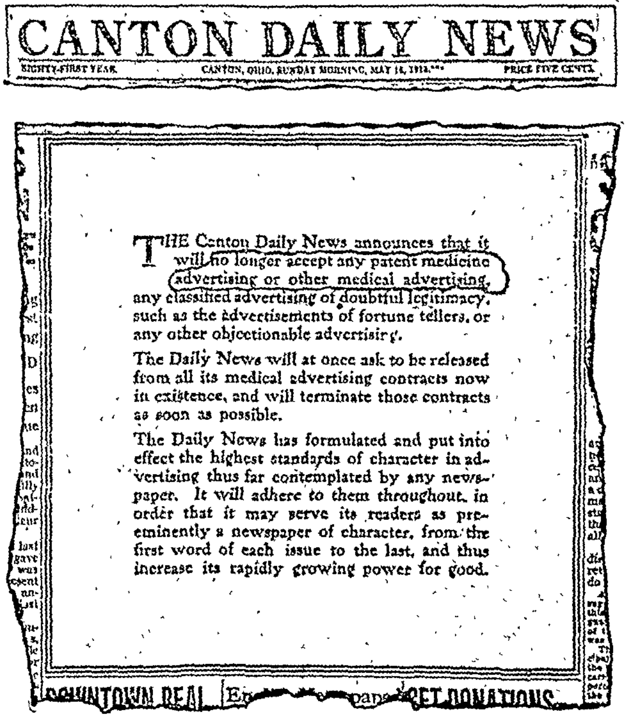
The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

AND STILL THEY COME

Another Daily Paper Rejects All Patent Medicine Advertisements

And now it is the Canton (Ohio) *Daily News!* In its issue of May 15, 1915, this paper announced that it would "no longer accept any patent medicine advertising or other medical advertising" for its pages. It gives among its reasons for taking this step, first, that it seeks to be a newspaper of character and strives for high ideals; second, that it recognizes a growing sentiment that newspapers must be judged as a whole by the standard of their advertising columns as well as by the standard of their news and editorial columns, and third, that it realizes that "advertisements are known by the company they keep" and the *Daily News* wishes its advertisements to be favorably known. Its editorial attitude toward the "patent medicine" business is thus expressed:



CANTON DAILY NEWS

EIGHTY-FIRST YEAR. CANTON, OHIO, SUNDAY MORNING, MAY 16, 1915. PRICE FIVE CENTS.

THE Canton Daily News announces that it will no longer accept any patent medicine advertising or other medical advertising, any classified advertising of doubtful legitimacy, such as the advertisements of fortune tellers, or any other objectionable advertising.

The Daily News will at once ask to be released from all its medical advertising contracts now in existence, and will terminate those contracts as soon as possible.

The Daily News has formulated and put into effect the highest standards of character in advertising thus far contemplated by any newspaper. It will adhere to them throughout, in order that it may serve its readers as preeminently a newspaper of character, from the first word of each issue to the last, and thus increase its rapidly growing power for good.

> "The *Daily News* believes that patent medicines, taken in the bulk, are an evil. Therefore they should not exist. The *News* has never heard any one argue to the contrary and it does not believe there are any arguments to the contrary. It has already received many endorsements of its stand, and no criticism.
>
> "Some patent medicines are the most vicious products of our time. They promise cures for incurable diseases. They cost lives by standing in the way of proper treatment of diseases which are curable by such treatment. They act as substitutes for liquor where liquor is barred. They create drug fiends.
>
> "Such patent medicines as these are vipers that ought to be crushed, must be crushed and WILL be crushed. They prosper largely because they are advertised in newspapers, magazines and other mediums. They are advertised because these mediums make money by advertising them. This is a source of revenue which the *News* is only too glad to forego. The day will come when all newspapers, whether they want to or not, will be compelled to do without this blood money."

The *Daily News* explains that it has, in the past, attempted to censor "patent medicine," advertising because it recognized the evils of many "patent medicines." It was not, however, satisfied with the way such censorship worked.

> "It is hard to know where to draw the line. More, it is IMPOSSIBLE to know where to draw the line. The *News* has reached the conclusion that the only remedy for the patent medicine evil is not regulation but prohibition—the prohibition of ALL patent medicine advertising. Therefore it takes this step."

Again, we of the medical profession should turn our attention to those publications for which we as a profession are directly responsible—the medical journals. Publishers of medical journals were for years in the same position with respect to proprietary medicine advertisements that the publishers of newspapers are today in respect to "patent medicine" advertisements. They were unable to separate the meritorious from the worthless, the useful from the fraudulent. The medical profession, through its own organization, the American Medical Association, created a body of experts—the Council on Pharmacy and Chemistry—which investigates and reports on the proprietary products that are submitted to the medical profession. The medical journal publisher of today, therefore, is in a position intelligently, fairly and scientifically to censor his advertisements of proprietary products. *That in many instances he still refuses to do so* is more than a reflection on the good faith of the individual publisher, it is a reproach on the good judgment of the profession which fails to lift its voice in demanding that such censorship be exercised. Once more it must be said, that, to the discredit of the medical profession, the general standard of medical journal advertising is below the standard of advertising in decent newspapers and immeasurably below the standard of advertising in the average high-class lay magazine.

CAUSE FOR OPTIMISM

A Clean Medical Journal —the South Texas Medical Record

The preceding article comparing the advertising standards of lay publications with those of medical journals may seem pessimistic. Fortunately, there are forces at work in the medical profession that make for optimism. An editorial in the last issue —April, 1915—of the *South Texas Medical Record*, the official organ of the South Texas District Medical Association, is especially significant. While not a large journal, the *South Texas Medical Record* could well stand as an example to medical publications of a much more pretentious character. Its advertising pages are above reproach and the journal is a credit alike to its editors and to those members of the profession whose support make its existence possible. In the editorial referred to, entitled, "Honest Advertising—Let us Cleanse Our Own Linen First," the editor-in-chief, Dr. W. Burton Thorning, says:

> "A recent editorial, entitled 'Honest Advertising,' in a daily newspaper, furnished the occasion for an editorial comment in the January number of the *Southwestern Hospital Reporter*. The latter, while taking the ground that the newspaper was inconsistent in uttering high editorial sentiments and in adjoining columns printing patent medicine advertisements, implied that newspaper men should be allowed some latitude in the matter of accepting advertising, on the plea of being laymen and therefore not expected to possess the same amount of information concerning patent 'dope' that medical men have.
>
> "It would appear to be a fair assumption that a layman, even though a highly educated and able editor of a great newspaper, does not know, and cannot be expected to know, the depth of depravity to which the consumption cure faker and the cancer quack can descend.
>
> "Granting that the newspaper man accepts the advertisements through ignorance of the facts concerning their possibilities for evil, what can be offered in defense of the medical editor who accepts advertising matter equally pernicious in its influence?

"Indeed, it is not so many years since many of the so-called ethical medical journals carried the ads of some of the most notorious quacks this country has ever known.

"Doubtless there are few, if any, who do so at the present time, but, on the other hand, there are only a few who do not advertise unethical institutions, and questionable proprietary medicines. As a matter of fact some of the most widely advertised patent medicines of today were formerly advertised as ethical proprietaries in medical periodicals, the great majority of which are still serving as a sort of preparatory school for advertisements that will presently appear in the lay press.

"What shall be offered in defense of the medical publication which continues to publish the advertising matter of hundreds of proprietaries which the Council on Pharmacy and Chemistry of the American Medical Association has shown to be either generally worthless or an out and out fake?

"Can the medical editor plead ignorance? Hardly. To do so would be to admit utter incapacity. There is only one inference to be drawn; the publication needs the money and is not over particular regarding its source.

"There is a remedy, however, a remedy absolutely certain in its results. If every physician in the United States for a period of three months would positively refuse to receive at his desk a medical journal containing questionable advertising, this blotch on medical journalism could be erased.

"It is true that many of them would sink, never to rise again, but the profession would be better off without those whose existence depends upon 'phoney' advertising. There are, unfortunately, several American journals whose reading pages are well and carefully edited and a credit to medical literature, whose advertising pages carry such undesirable matter that the educated physician can only feel a sense of disgust.

"Such journals could very well succeed on the quality of their reading matter and undoubtedly would increase their circulation enough to more than offset the loss in advertising."

Correspondence

The Defervescence in Typhus Fever

To the Editor:—May I add my experience in corroboration of your statement in a recent Current Comment, on this subject (The Journal, May 15, 1915, p. 1664) that the fever of typhus terminates in a great proportion of cases by lysis and not by crisis? The three typhus epidemics which I observed in Russia have given me sufficient material to support that statement. As a rule, the fever terminates on the twelfth, fourteenth or seventeenth day, the drop in temperature occupying from twelve to seventy-two hours. Even in the rare cases in which the fever ends abruptly, the temperature curve is seldom like the typical curve of lobar pneumonia. It may be worth mentioning that in children in whom the disease is nearly always mild, critical defervescence hardly ever occurs.

G. A. Friedman, M.D., New York.

Effect on Membership of Removal from State

To the Editor:—I enclose a copy of a resolution which was adopted by the Medical Society of the District of Columbia at a recent meeting, with the request that it be published in The Journal of the American Medical Association.

A. L. Hunt, M.D., Corresponding Secretary,
Washington, D. C.

Moved, that the Executive Committee recommends to the Medical Society of the District of Columbia the adoption of the following resolutions, with instructions that copies thereof be sent to the delegates, presidents and secretaries of the various state medical associations; that it be printed in the *Washington Medical Annals;* and that a copy be sent to The Journal of the American Medical Association with request for its publication therein.

Whereas, Section 3, Chapter VIII, of the By-Laws of the American Medical Association provides as follows:

Effect on Membership of Removal to Another State: A member who changes the location at which he practices medicine from the state through whose constituent association he holds membership in the American Medical Association to another state in which there is a constituent association is eligible to membership in the component society of his new location upon the presentation of a transfer card and an official statement that his dues have been paid in full in the society in which he holds membership. He shall forfeit his membership in the American Medical Association one year after such change of location, unless he becomes a member of the constituent association of the state to which he has moved. Provided, however, that if the component society into whose territory such member has moved shall refuse him membership, the member shall be privileged to appeal to the Judicial Council of this Association to determine whether or not he be guilty of any act that warrants the enforcement of the provisions of this section. Pending the decision of such appeal, he shall retain his membership in the American Medical Association through his original state association. And provided, further, that the term "the practice of medicine" throughout these by-laws shall be held to mean the offering of service or counsel for the relief of those suffering from abnormal physical or mental conditions. Provided, that nothing in this section shall be construed as exempting any member of the American Medical Association from compliance with the requirements of the civil laws of the state or district into which he may have been removed.

Be it *Resolved,* That the Medical Society of the District of Columbia is opposed to the foregoing section, for the following reasons:

The section is loosely and clumsily worded, and contains provisions of questionable relevancy or practicability. The proviso relating to appeal to the Judicial Council seems meaningless, as it does not appear what "the provisions of this section" are that are to be enforced, or how they are to be enforced. According to the apparent intent, the operation of the section, if enforceable, could have the effect of compelling local and constituent associations against their will to admit members by transfer from other jurisdictions. This method of admitting members by transfer is not contemplated by the procedure prescribed in the constitution of this society, or doubtless in the constitutions of many other state associations; hence the virtual effect of this section is autocratically to override and nullify in this respect these constitutions without the consent of the local associations, and even without consulting them. The adherence to the general plan of organization of the American Medical Association required of the constituent associations cannot be construed as granting unlimited control over local affairs. Absolute, complete and unrestricted control over admission to its own membership is a fundamental right vital to the autonomy of any organization. That three outsiders, however excellent, members of the Judicial Council, should have the appellate power to dictate to the hundreds of members of a constituent association as to the admission of new members is totally repugnant to the approved American principle of local self government. Their familiarity with local conditions and local spirit makes the members of a local association far better qualified to act in their own way on applicants for membership than any outside tribunal; their decision should be final, and it is not likely that material injustice will be done. Furthermore, if the right of the American Medical Association to encroach on local prerogatives and override local constitutions in one matter is conceded, there is not a limit to the autocratic interference with personal and local independence and privileges to which it or its managers might not attempt to lay claim. For the foregoing reasons the Medical Society of the District of Columbia is not disposed to recognize any authority, jurisdiction or power of interference whether on the part of the American Medical Association or its Judicial Council with respect to the admission of members or any other purely local matter. Therefore, be it

Resolved, That the delegate of this society to the American Medical Association is instructed to offer and promote the adoption of some such substitute as the following for the foregoing Section 3, Chapter VIII of the By-Laws, which should amply meet the requirements of the case.

Removal of Members.—A member of a constituent association removing from the jurisdiction thereof may remain eligible for membership in the American Medical Association for a period of eighteen months following such removal, after which such eligibility shall cease, unless or until it is reestablished by his becoming a member of the constituent association of the jurisdiction in which he is located.

Strychnin Symptoms After Large Doses of Morphin

To the Editor:—That large doses of morphin may produce symptoms resembling those caused by strychnin can be seen not only from the recent experimental work of Hugh McGuigan and E. L. Ross (The Journal, May 1, 1915, p. 1494) but also from the following observations. In the *Philadelphia Medical Journal,* March 21, 1903, I published the following record under the title, "Spinal Symptoms Caused by Acute Morphine Poisoning":

A middle-aged man in one of his usual attacks of rheumatic pain from which he had been a sufferer for several years went to a nearby pharmacy for relief. A mixture containing 3 grains of morphin sulphate was given him. He drank over a half of it at once. Half an hour later he suddenly became pale and fell in a semicomatose state. Some clonic contractions in the upper extremities and trismus made their appearance which, however, did not last long. A vomitive was given him before my arrival. I found him pale, covered with perspiration and unable to walk. When forced to take a few steps, spastic paralysis was evident. The knee-jerks were markedly increased; ankle-clonus and Babinski toe phenomenon were present. Seventeen hours later all symptoms of motor irritability disappeared.

In the *Philadelphia Medical Journal,* March 28, 1903, W. W. Keen, commenting on my communication, reports his own experience with morphin. In 1866, he says, he had a severe attack of insomnia. In desperation one night he took one-quarter grain of morphin and repeated the dose in an hour. He not only did not sleep, but an hour or two later he walked with a spastic gait. When he accidentally struck his knee against an article of furniture in the room in the dark, instantly a spasm closely resembling a strychnia spasm was produced. Alfred Gordon, M.D., Philadelphia.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SERUMS AND VACCINES IN ERYSIPELAS

To the Editor:—What is the consensus of opinion of the medical profession as to the serum treatment of erysipelas. What is the dosage and how often given? Have any bad results occurred? Please sign initials only. E. R. S.

Answer.—Antistreptococcus serum has been used in erysipelas with apparently good results in some cases. But as Kolmer says (Infection, Immunity and Specific Therapy), "with very indifferent results." Erdmann (Reference Handbook of the Medical Sciences, iv, 89) states: "Marmorek's and other antistreptococcus serums have failed. Autogenous and stock vaccines made from erysipelas streptococci demonstrated no efficiency in a series of ninety-five of my cases so treated." The general opinion seems to be that the evidence as to the usefulness of these serums is not convincing. However, Ashurst (Principles and Practice of Surgery) says: "Antistreptococcic serum is harmless and, if possible, should be administered in all severe cases." The treatment by vaccines was inefficient in the hands of Erdmann, but some authors have thought it useful. Maynard Smith (System of Treatment, edited by Latham and English) says: "Its results have been very promising and it is likely to form the most reliable means at our disposal. In severe cases an initial dose of 10 millions of the dead organisms is given. On the following day another dose of 10 millions is administered if there is improvement in clinical manifestation; if not, a smaller dose of 5 millions is given."

The treatment with vaccines must be regarded as still on trial.

LITERATURE ON SCOPOLAMIN

To the Editor:—Please give me information as to the physiologic action and therapeutic indications of scopolamin, and some literature on the subject. Morris Schott, M.D., Cleveland.

Answer.—The following is a list of articles dealing with scopolamin:

Hatcher, Robert A.: Scopolamin and Morphin in Narcosis and in Childbirth, The Journal, Feb. 5, 1910, p. 446; Feb. 12, 1910, p. 516.
Morphin and Hyoscin (Scopolamin) in Labor, Queries and Minor Notes, The Journal, June 7, 1913, p. 1814.
Scopolamin in Obstetrics, Queries and Minor Notes, The Journal, Aug. 31, 1912, p. 758.
Franck: Case of Addiction to Scopomorphin, *München. med. Wchnschr.,* April 2, 1912.
Scopolamin (Hyoscin) and Morphin as an Anesthetic, Therapeutics, The Journal, Dec. 16, 1911, p. 1995.
Langer, H.: Scopolamin Solutions Do Not Keep Well and Should Be Made Fresh, *Therap. Monatsh.,* February, 1912.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 6. Chairman, Dr. W. H. Sanders, Montgomery.
Alaska: Juneau, July 6. Sec., Dr. Harry C. DeVighne, Juneau.
Arizona: Phoenix, July 6-7. Sec., Dr. John Wix Thomas, Phoenix.
California: San Francisco, June 15-18. Sec., Dr. Charles B. Pinkham, 727 Butler Bldg., San Francisco.
Delaware: Dover and Wilmington, June 15-17. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.
Florida: Jacksonville, June 15-16. Sec., Dr. E. W. Warren, 102 Front St., Palatka.
Georgia: Atlanta and Augusta, June 2-4. Sec., Dr. C. T. Nolan, Marietta.
Illinois: Chicago, June 24-26. Sec., Dr. C. St. Clair Drake, Springfield.
Iowa: Iowa City, June 10-12. Sec., Dr. G. H. Sumner, Capitol Bldg., Des Moines.
Kansas: Kansas City, June 8-10. Sec., Dr. H. A. Dykes, Lebanon.
Kentucky: Louisville, June 8-10. Sec., Dr. A. T. McCormack, Bowling Green.
Louisiana: New Orleans, June 3-5. Sec., Dr. E. L. Leckert, 716 Machea Bldg., New Orleans.
Maine: Augusta, July 6-7. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.
Maryland: Baltimore, June 21. Sec., Dr. J. McP. Scott, Hagerstown.
Maryland: Homeopathic, Baltimore, June 15-16. Sec., Dr. O. N. Duvall, 1817 N. Fulton Ave., Baltimore.
Michigan: Ann Arbor, June 8-10. Sec., *Dr. B. D. Harison, 504* Washington Arcade, Detroit.
Minnesota: Minneapolis, June 1-4. Sec., Dr. Thomas McDavitt, Lowry Bldg., St. Paul.
Mississippi: Jackson, June 15-16. Sec., Dr. E. H. Galloway, Jackson.
Missouri: St. Louis, June 21-23. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.
Nebraska: Lincoln, June 10-11. Sec., Dr. H. B. Cummins, Seward.
New Hampshire: Concord, July 6-7. Regent, Mr. H. C. Morrison, Concord.
New Jersey: Trenton, June 22-23. Sec., Dr. H. G. Norton, 429 E. State St., Trenton.
New York: Albany, Buffalo, New York and Syracuse, June 29-July 2. Mr. Harlan H. Horner, Chief, Examination Division, State Education Bldg., Albany.
North Carolina: Greensboro, June 8. Sec., Dr. H. A. Royster, Raleigh.
North Dakota: Grand Forks, July 6-9. Sec., Dr. G. M. *Williamson,* Grand Forks.
Ohio: Columbus, June 8-11. Sec., Dr. George H. Matson, Columbus.
Oregon: Portland, July 5. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.
Pennsylvania: Philadelphia and Pittsburgh, June 1-3. Sec., Dr. Nathan C. Schaeffer, Harrisburg.
Rhode Island: Providence, July 1. Sec., Dr. Gardner T. Swarts, State House, Providence.
South Carolina: Columbia, June 8. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.
Tennessee: Memphis and Nashville, June 25, 26. Sec., Dr. A. B. De Loach, 426 Scimitar Bldg., Memphis.
Texas: Austin, June 22-24. Sec., Dr. M. P. McElhannon, Belton.
Utah: Salt Lake City, July 5. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.
Vermont: Burlington, July 1-3. Sec., Dr. W. Scott Nay, Underhill.
Virginia: Richmond, June 22-25. Sec., Dr. J. N. Barney, Fredericksburg.
Washington: Seattle, July 6. Sec., Dr. G. N. Suttner, Baker Bldg., Walla Walla.
Wisconsin: Milwaukee, June 29-30—July 1. Sec., Dr. J. M. Beffel, 3200 Clybourn St., Milwaukee.

Maine March Report

Dr. Frank W. Searle, secretary of the Maine State Board of Registration of Medicine, reports the written examination held at Portland, March 9-10, 1915. The total number of subjects examined in was 10; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 16, of whom 13 passed and 3 failed. One candidate was licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Medical School of Maine	(1913)	81
College of Physicians and Surgeons, Baltimore	(1911)	76
Maryland Medical College	(1909)	81
College of Physicians and Surgeons, Boston	(1913)	88
Harvard University	(1912) 91; (1913) 80; (1915)	84
Tufts College Medical School	(1911) 79; (1913)	80
New York Homeo. Med. Coll. and Flower Hospital	(1914)	85
University and Bellevue Hospital Medical College	(1906)	77
University of Tennessee	(1912)	91
University of West Tennessee	(1913)	78

FAILED		
Eastern University*	(1913)	65
College of Phys. and Surg., Boston	(1909) 77†; (1912)	69

* This college is officially reported as not recognized by the Maryland State Board of Medical Examiners.

† Conditioned in one subject.

Arizona April Report

Dr. John Wix Thomas, secretary of the Arizona Board of Medical Examiners, reports the written examination held at Phoenix, April 6-7, 1915. The total number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 7, of whom 3 passed, including 1 osteopath, and 4 failed, including 1 osteopath. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Rush Medical College	(1914)	80.4
University of Vienna, Austria	(1910)	77.8
FAILED		
University of the South	(1897)	45.5
Vanderbilt University	(1914)	73.4
National School of Medicine, Mexico	(1910)	43.6

Book Notices

THE TUBERCULOSIS NURSE. Her Function and Her Qualifications. A Handbook for Practical Workers in the Tuberculosis Campaign. By Ellen N. La Motte, R.N., Graduate of Johns Hopkins Hospital. Introduction by Louis Hamman, M.D., Physician in Charge Phipps Tuberculosis Dispensary, Johns Hopkins University. Cloth. Price, $1.50. Pp. 292. New York: G. P. Putnam's Sons, 1915.

This book deals with the tuberculosis situation in Baltimore. It details the problems that have presented themselves in that city, how they have been solved, and how an effective nursing staff has been built up, first under private and later under municipal control. The situation in other cities and countries is not considered. This, however, in no way detracts from the value of the book. The author believes that only graduates of first-class general hospitals should be employed as visiting tuberculosis nurses, and advises strongly against employing women who have apparently recovered from the disease. In Baltimore the applicant for a position in this service is required to submit to examination by a specialist; a certificate of health from her family physician is not accepted. The hardships and difficulties in the work are considered and the necessity for education of patients and their families. The social and economic aspects of tuberculosis relief work are considered at some length. The author believes that the social service worker has an important place in this work, but calls attention to the fact that some social workers try to do their own and every one else's work as well. "All social workers should learn where to stop—where to transfer the case to some one else better fitted to deal with another phase of it."

TRANSACTIONS OF THE FOURTH INTERNATIONAL CONGRESS ON SCHOOL HYGIENE. Five Volumes. Paper. 1913.

The Fourth International Congress on School Hygiene held at Buffalo, Aug. 25 to 30, 1913, was admittedly one of the most successful of international conferences on this subject. The Transactions fill five large volumes and contain a large amount of valuable material that will be utilized by all those interested in any aspect of the school hygiene field. Specific mention of the many valuable papers presented is impossible on account of their great number. The five volumes form a mine of valuable material that will justify the careful study of all those interested in school hygiene. The program includes practically every phase of school hygiene, so that the teacher, the physician, the school inspector, the local health officer and the school superintendent can all find much material of interest. Paradoxical as it may seem, perhaps the most pertinent criticism that can be made on the Transactions is that they are too complete. Their very bulk is appalling and prevents one from finding many things that would doubtless be of value. While custom has sanctioned the habit of including in transactions of these congresses practically everything that has any connection with the case, there are some of these customs which would be far more honored in the breach than in the observance. For instance, it is difficult to understand why volumes of transactions should contain many pages of names of committees, delegates, exhibitors, etc., why space should be given to such purely conventional utterances as the perfunctory addresses of welcome delivered by mayors and governors and to equally perfunctory responses thereto. What object is there in printing in transactions, issued months after the congress, such transient matters as reports of entertainment, reception and transportation committees, lists of hotels with rates, etc.? The editorial blue pencil, if liberally used, would have reduced the five volumes of Transactions to one or two and would greatly have increased the value of the surviving material. These international congresses are undoubtedly of great value, and the material presented is in the main thoroughly worthy of preservation; but there would be less likelihood of such Transactions reposing undisturbed on library shelves if the enthusiasm of those responsible for the preparation of these Transactions were somewhat tempered by discrimination.

URINARY ANALYSIS AND DIAGNOSIS BY MICROSCOPICAL AND CHEMICAL EXAMINATION. By Louis Heitzmann, M.D. Third Edition. Cloth. Price, $3 net. Pp. 345, with 131 illustrations. New York: William Wood & Co., 1915.

In the present revision, "the aim has again been to increase and improve the first part on chemical examination and to incorporate in it all the simpler methods and tests which have proven of value." With few exceptions the more complicated tests have been omitted. As in the former editions, special emphasis is laid on the microscopic examination and its importance in diagnosis. While there is no question that a careful study of the urinary epithelia may often lead to presumptive, and occasionally to an absolute differential diagnosis, it seems likely that Heitzmann has taken too radical a position regarding the importance of the epithelia in diagnosis. The sections dealing with these points are especially complete and worthy of careful attention by the reader. This well-known book, while not so complete as could be desired with reference to the chemical examination of the urine, is, nevertheless, adequate for all who do not wish to undertake the more detailed special examinations. Its chief value lies in its thorough presentation, both in the text and in the excellent original illustrations, of the microscopic characteristics of the urine and, especially, of the value of such examinations in differential diagnosis.

DIE FÄZES DES MENSCHEN IM NORMALEN UND KRANKHAFTEN ZUSTANDE MIT BESONDERER BERUCKSICHTIGUNG DER KLINISCHEN UNTERSUCHUNGSMETHODEN. Von Prof. Dr. Ad. Schmidt, Geh. Medizinalrat, and Prof. Dr. J. Strasburger, Ordentl. Professor der Inneren Medizin. Fourth Edition. Paper. Price, 22 marks. Pp. 444, with 31 illustrations. Berlin: August Hirschwald, 1915.

Since the appearance of the former edition of this authoritative work, investigation of the feces has become more complex. For this reason the additions to the text and bibliography have been numerous. Especial attention should be directed to the section on the micro-organisms of the feces, as herein may be found a clear discussion of the occurrence and differentiation of the various types of bacteria which are observed in the intestinal tract both in health and disease. The section dealing with the chemical analysis of the feces is also particularly complete, and should lead the worker to a much more complete technic than is usually employed. This work may be recommended to the laboratory worker who has occasion to examine and study the feces, and to the general practitioner who may desire to obtain a better understanding of methods of study, as well as of the proper interpretation of the analytic findings in this much neglected field.

Medicolegal

Making a Public Nuisance of Milk Pasteurization—Criminal Intent

(People vs. Borden's Condensed Milk Co. (N. Y.), 151 N. Y. Supp. 547)

The Supreme Court of New York, Appellate Division, Second Department, affirms a judgment holding the defendant guilty of having committed the crime of maintaining a public nuisance in its method of pasteurizing milk. The court says that the defendant claimed that all the acts or omissions charged against it were merely incidental to the process of "pasteurization," and that therefore its acts or omissions had statutory sanction and could not be considered as constituting a public nuisance in a legal sense. It may be granted at once that the ordinance of the board of health had the force of a statute, for the Greater New York Charter so provides. But this ordinance did not purport to prescribe nor to authorize any detail in the act of "pasteurization," such as was charged against the defendant in this proceeding. It did require "pasteurization" generally, but it is very far-fetched to think that this requirement authorized, much less directed, the making of unnecessary noises in the very early hours of morning, either within or without the defendant's plant, and to the great annoyance of the residents of the neighborhood. The defendant urged further that the judgment was reached by ignoring the necessity of proving a criminal intent on the part of the defendant, and that therefore it was based on a substantial error of law. What is meant by the phrase "criminal intent," within the scope of the definition of the crime of maintaining a public nuisance? It does not mean that one who is charged with the commission of that offense should be shown to have consciously and positively intended to interfere with the comfort and repose of "any considerable number of persons." His criminality is independent of any positive purpose of annoyance. It can arise as well from his very failure to think of anybody but himself, and, generally, public nuisances, whenever and wherever they exist, arise from just such self-concentration. The acts involved here were so continuous and persistent as to indicate on the part of the defendant's employees a complete indifference to the rights of others and, as to the crime now under consideration, to establish a "criminal intent" within the meaning of the law.

Injury to Previously Injured Person—Distinction Between Hypothetical and Other Questions

(Blake vs. City of Bedford (Ia.), 151 N. W. R. 74)

The Supreme Court of Iowa affirms a judgment for $2,750 in favor of the plaintiff, a man about 60 years old, who was injured on a defective sidewalk more than nine months after he had been injured by a fall from a ladder. The court says that the fact that the plaintiff had sustained a prior injury was of course material, but it constituted no defense to this action, if he succeeded in showing to the jury, that, by reason of the defendant's negligence with respect to its sidewalk, he was made to fall, without fault on his part, and thereby received other or additional or increased injury. A physician who was shown to have personally examined and treated the plaintiff for his injuries was asked for his opinion whether a union, bony or fibrous, of the broken bone had taken place prior to the plaintiff's fall on the sidewalk. In this question the witness was asked, among other things, to speak from his examination and observation of the patient. It was urged that the witness should not have been allowed to answer until he had first detailed to the jury all that he had learned or discovered in his examination and treatment of the patient. But such is not the rule. If a witness is testifying purely as an expert, pronouncing an opinion solely on a hypothetical state of facts, then of course it is the right of the opposing party to insist that the question shall disclose all the facts on which the opinion is to be pronounced. But, if the witness be a physician who professes to speak from his personal observation, examination, and treatment, he may properly express an opinion based thereon, it being, of course, the privilege of counsel on the other side, by cross-examination, to test its accuracy and reasonableness.

Information Not Obtained for Purpose of Treatment Is Not Privileged

(Cherpeski vs. Great Northern Railway Co. (Minn.), 150 N. W. R. 1091)

The Supreme Court of Minnesota, in reversing a judgment obtained by the plaintiff for personal injuries, holds that it was error to exclude the testimony of two physicians called as witnesses by the defendant. One of them was a physician and surgeon of the Northwestern Road. The defendant proposed showing that the plaintiff went to him and was examined for the purpose of ascertaining whether he could enter the service of the road. The other physician was the general surgeon of the defendant. The plaintiff, according to the offered proof, went to him to ascertain whether he was physically able to remain in the service of the company. In neither case was curative treatment contemplated. In neither case did the physician obtain information to enable him to prescribe or act for the plaintiff. Objections to the proposed testimony were sustained on the ground that the information sought was privileged. But from the showing made or offered to be made the court thinks it affirmatively appeared that the information obtained by the two physicians was not privileged. At common law communications between physician and patient or information obtained by the physician in treating his patient were not privileged. The privilege comes from the statute.

Injury from Negligently Cutting Through Bandage—Care Required in Public Dispensary

(Volkell vs. Wolf (N. Y.), 151 N. Y. Supp. 918)

The Supreme Court of New York, Appellate Term, First Department, which affirms a judgment in favor of the plaintiff, amount not stated, says that the defendant, a surgeon, operating in a dispensary, inflicted an injury on this infant plaintiff while cutting through a bandage in which the child's broken arm was wrapped. The defendant claimed that, if the bandage had been adjusted properly and in the usual fashion, the patient's hand would have been fastened tightly to the body and in no danger of being cut. He admitted that before cutting he made no examination to ascertain where the hand was, or what was concealed under the point where he applied the shears, claiming that "he had a right to assume that it (the bandage) was properly put on; also that, "I think the whole hand was exposed, but I did not see it; I had the impression that the bandage was outside of the upper part;" also that it was merely good fortune that the infant's hand was not cut off. The hurry of work in a public dispensary does not excuse the lack of ordinary care. The defendant could not assume that the hand was in a safe position, and rely on that, when the fact could be readily ascertained by himself before applying the shears. The finding of negligence was warranted by the evidence.

What Constitutes Removal of Hand at Wrist

(Moore vs. Aetna Life Insurance Co. (Ore.), 146 Pac. R. 151)

The Supreme Court of Oregon affirms a judgment for the plaintiff, where the question was disputed as to whether his hand had been removed at the wrist. The court says that the question was one of extreme nicety, and there is a dearth of decisions covering the exact point, there being no case cited by counsel or discovered by the court involving the construction of a policy exactly identical in its terms with the one on which this action was predicated. This was an action to recover on an accident insurance policy, which provided that the plaintiff should be entitled to recover $1,000 if he should suffer accidental injuries resulting in the "loss of a hand by removal at or above the wrist." The plaintiff was accidentally shot in the hand, necessitating the removal of all the bones of the hand at the wrist except the metacarpal bone of the thumb. From the medical testimony, which was meager, and photographs taken about the time of the trial, it appears that the amputation began at the *inner side of*

the left wrist, removing probably a small portion of the unciform bone, and including in the operation all the metacarpal bones of the four fingers at their articulation with the unciform, os magnum, and trapezoid, respectively. The os magnum, trapezoid, and trapezium were clearly left intact, and the bones of the thumb, while possibly injured by the shot, retained their continuity. The thumb itself was not removed, although the ball of that member was partially destroyed and the ligaments so injured that it was stiff and entirely useless. The medical witness stated that in his opinion it would have been better to have removed what remained of the thumb, so that the plaintiff could have had an artificial hand. There was enough of the flesh of the hand to cover the bones of the wrist, forming what the medical witness termed "a bunch of hardened callus" at the end of the wrist, probably no more than good surgery would require for the protection of the bones of the wrist. The court is of the opinion that the plaintiff was within the true meaning and spirit of the policy. He had a good hand against losing the use of which he desired to insure. If he had been told the intent and meaning of the policy was such that if in case of a necessary amputation the surgeon should leave some useless shred of his hand to be a source of annoyance and inconvenience, and thereby his policy would be practically worthless, does any sane person believe for a moment he would have taken out the policy? The substance of what he sought was insurance against the possible loss of his hand as a useful member of his body. Substantially he lost his hand by removal at the wrist.

AMERICAN GASTRO-ENTEROLOGICAL ASSOCIATION

Eighteenth Annual Meeting, held at Baltimore, May 10, 1915

The President, Dr. Joseph C. Bloodgood, in the Chair

Benign Growths of the Stomach

Dr. Seymour Basch, New York: Only the genuine new growths are considered. They include mucous polypi, adenomas, lymphadenomas, myomas, fibromas, lipomas, myxomas, osteomas and cysts. When the mucous membrane is not involved and there is no obstruction from the growth, normal conditions of the gastric secretion should prevail.

DISCUSSION

Dr. Jacob Kaufmann, New York: A patient whom I had occasion to see several times with her physician, a girl, suffered from her fourteenth to her nineteenth year with repeated gastric hemorrhages of very severe type, occurring shortly before menstruation. Roentgenograms made on two occasions showed the characteristic picture of penetrating ulcer of the duodenum. At operation, the duodenum and pyloric part of the stomach were found normal, but fibroma was discovered at its cardiac end. The mucous membrane around it was quite congested, and when the tumor was handled, a profuse hemorrhage was produced. I think we have every reason to pronounce this a true case of menstrual bleeding from the stomach.

Dr. Henry W. Bettmann, Cincinnati: A man, now about 50 years of age, has suffered for fifteen years with pain and hyperacidity of the stomach. Nine years ago, an operation was done, and the whole mucous membrane was found covered with small polyadenomas. We did nothing but sew up the stomach again. He will probably go on for the rest of his life suffering from the same symptoms. The supposed rarity of these cases may be due to the fact that we have failed to put isolated cases of this character on record.

Dr. John A. Lichty, Pittsburgh: I should like to ask Dr. Basch whether he relies largely on the Roentgen ray in making the diagnosis. The slides he has exhibited seem to show a rather large shadow. In cases of small polypi, however, I can hardly see how the Roentgen ray would help.

Dr. Seymour Basch, New York: The Roentgen ray is a distinct advance in the diagnosis of borderline cases. Roentgenograms show not only a distinct shadow defect caused by the penetration of the tumor into the bismuth, but also a notched appearance.

The Cause of the Variations in the Gastric Hunger Contractions with Age

Dr. T. L. Patterson, Baltimore: By starving young and old animals, it is possible to show that in very young dogs the contractions of the empty stomach are practically continuous, while in old animals there is a decrease in the gastric hunger activity proportional to the advance in age. Gastric hunger variations appear in the gastric tonus, in the strength and rapidity of the hunger contractions, and especially in the duration of the hunger and quiescence periods of the stomach, the cause of which is produced by two differentiated factors, namely, age and rate of metabolism. The gastroneuromuscular apparatus is independent of the central nervous system. In prolonged starvation, the hunger sensation may be lost, while the hunger contractions persist.

DISCUSSION

Dr. Ludwig W. Kast, New York: Is there any relation between the hunger contractions and the gastric secretion?

Dr. Joseph C. Bloodgood, Baltimore: In these experiments, did Dr. Patterson differentiate between the different groups by restricting all food and liquid in one group, and restricting food alone in the other? If so, I should like to know whether there was any difference in the contractions when the animals had all the water they wanted.

Dr. T. L. Patterson, Baltimore: Regarding the relation between the gastric hunger contractions and the gastric secretion, anything that comes in contact with the gastric mucosa will inhibit the gastric hunger contractions at once whether it be water or food. The hunger contractions do not seem to have much effect on the gastric secretion. All the animals had free access to water, but had no food.

The Effect of Certain Gastric Conditions on the Salivary Secretion

Dr. T. R. Brown, Baltimore: Our studies show that the chewing of bland substances produces a considerable flow of saliva, which is quite rich in diastatic ferment. A comparison of normal cases with cases in which there was increased, diminished or absent hydrochloric acid showed that there were no variations from the normal in respect to quantity, alkalinity or diastatic ferment content of the saliva sufficiently great to make us feel that there is any definite relationship between the character of the gastric juice and that of the saliva. It does not appear probable that quantitative or ferment changes in the saliva play any considerable part in the development of the glossitis, gingivitis or stomatitis, so frequently met in a case of achylia gastrica.

Dr. E. B. Freeman, Baltimore: In one of our cases of achylia due to carcinoma of the stomach, the diastase test was positive, and also in a case of hyperacidity, there being a large amount of diastase present in both cases.

Making a Public Nuisance of Milk Pasteurization—Criminal Intent

(People vs. Borden's Condensed Milk Co. (N. Y.), 151 N. Y. Supp. 547)

The Supreme Court of New York, Appellate Division, Second Department, affirms a judgment holding the defendant guilty of having committed the crime of maintaining a public nuisance in its method of pasteurizing milk. The court says that the defendant claimed that all the acts or omissions charged against it were merely incidental to the process of "pasteurization," and that therefore its acts or omissions had statutory sanction and could not be considered as constituting a public nuisance in a legal sense. It may be granted at once that the ordinance of the board of health had the force of a statute, for the Greater New York Charter so provides. But this ordinance did not purport to prescribe nor to authorize any detail in the act of "pasteurization," such as was charged against the defendant in this proceeding. It did require "pasteurization" generally, but it is very far-fetched to think that this requirement authorized, much less directed, the making of unnecessary noises in the very early hours of morning, either within or without the defendant's plant, and to the great annoyance of the residents of the neighborhood. The defendant urged further that the judgment was reached by ignoring the necessity of proving a criminal intent on the part of the defendant, and that therefore it was based on a substantial error of law. What is meant by the phrase "criminal intent," within the scope of the definition of the crime of maintaining a public nuisance? It does not mean that one who is charged with the commission of that offense should be shown to have consciously and positively intended to interfere with the comfort and repose of "any considerable number of persons." His criminality is independent of any positive purpose of annoyance. It can arise as well from his very failure to think of anybody but himself, and, generally, public nuisances, whenever and wherever they exist, arise from just such self-concentration. The acts involved here were so continuous and persistent as to indicate on the part of the defendant's employees a complete indifference to the rights of others and, as to the crime now under consideration, to establish a "criminal intent" within the meaning of the law.

Injury to Previously Injured Person—Distinction Between Hypothetical and Other Questions

(Blake vs. City of Bedford (Ia.), 151 N. W. R. 74)

The Supreme Court of Iowa affirms a judgment for $2,750 in favor of the plaintiff, a man about 60 years old, who was injured on a defective sidewalk more than nine months after he had been injured by a fall from a ladder. The court says that the fact that the plaintiff had sustained a prior injury was of course material, but it constituted no defense to this action, if he succeeded in showing to the jury, that, by reason of the defendant's negligence with respect to its sidewalk, he was made to fall, without fault on his part, and thereby received other or additional or increased injury. A physician who was shown to have personally examined and treated the plaintiff for his injuries was asked for his opinion whether a union, bony or fibrous, of the broken bone had taken place prior to the plaintiff's fall on the sidewalk. In this question the witness was asked, among other things, to speak from his examination and observation of the patient. It was urged that the witness should not have been allowed to answer until he had first detailed to the jury all that he had learned or discovered in his examination and treatment of the patient. But such is not the rule. If a witness is testifying purely as an expert, pronouncing an opinion solely on a hypothetical state of facts, then of course it is the right of the opposing party to insist that the question shall disclose all the facts on which the opinion is to be pronounced. But, if the witness be a physician who professes to speak from his personal observation, examination, and treatment, he may properly express an opinion based thereon, it being, of course, the privilege of counsel on the other side, by cross-examination, to test its accuracy and reasonableness.

Information Not Obtained for Purpose of Treatment Is Not Privileged

(Cherpeski vs. Great Northern Railway Co. (Minn.), 150 N. W. R. 1091)

The Supreme Court of Minnesota, in reversing a judgment obtained by the plaintiff for personal injuries, holds that it was error to exclude the testimony of two physicians called as witnesses by the defendant. One of them was a physician and surgeon of the Northwestern Road. The defendant proposed showing that the plaintiff went to him and was examined for the purpose of ascertaining whether he could enter the service of the road. The other physician was the general surgeon of the defendant. The plaintiff, according to the offered proof, went to him to ascertain whether he was physically able to remain in the service of the company. In neither case was curative treatment contemplated. In neither case did the physician obtain information to enable him to prescribe or act for the plaintiff. Objections to the proposed testimony were sustained on the ground that the information sought was privileged. But from the showing made or offered to be made the court thinks it affirmatively appeared that the information obtained by the two physicians was not privileged. At common law communications between physician and patient or information obtained by the physician in treating his patient were not privileged. The privilege comes from the statute.

Injury from Negligently Cutting Through Bandage—Care Required in Public Dispensary

(Volkell vs. Wolf (N. Y.), 151 N. Y. Supp. 918)

The Supreme Court of New York, Appellate Term, First Department, which affirms a judgment in favor of the plaintiff, amount not stated, says that the defendant, a surgeon, operating in a dispensary, inflicted an injury on this infant plaintiff while cutting through a bandage in which the child's broken arm was wrapped. The defendant claimed that, if the bandage had been adjusted properly and in the usual fashion, the patient's hand would have been fastened tightly to the body and in no danger of being cut. He admitted that before cutting he made no examination to ascertain where the hand was, or what was concealed under the point where he applied the shears, claiming that "he had a right to assume that it (the bandage) was properly put on; also that, "I think the whole hand was exposed, but I did not see it; I had the impression that the bandage was outside of the upper part;" also that it was merely good fortune that the infant's hand was not cut off. The hurry of work in a public dispensary does not excuse the lack of ordinary care. The defendant could not assume that the hand was in a safe position, and rely on that, when the fact could be readily ascertained by himself before applying the shears. The finding of negligence was warranted by the evidence.

What Constitutes Removal of Hand at Wrist

(Moore vs. Aetna Life Insurance Co. (Ore.), 146 Pac. R. 151)

The Supreme Court of Oregon affirms a judgment for the plaintiff, where the question was disputed as to whether his hand had been removed at the wrist. The court says that the question was one of extreme nicety, and there is a dearth of decisions covering the exact point, there being no case cited by counsel or discovered by the court involving the construction of a policy exactly identical in its terms with the one on which this action was predicated. This was an action to recover on an accident insurance policy, which provided that the plaintiff should be entitled to recover $1,000 if he should suffer accidental injuries resulting in the "loss of a hand by removal at or above the wrist." Making a Public Nuisance of Milk Pasteurization—Criminal Intent

(People vs. Borden's Condensed Milk Co. (N. Y.), 151 N. Y. Supp. 547)

The Supreme Court of New York, Appellate Division, Second Department, affirms a judgment holding the defendant guilty of having committed the crime of maintaining a public nuisance in its method of pasteurizing milk. The court says that the defendant claimed that all the acts or omissions charged against it were merely incidental to the process of "pasteurization," and that therefore its acts or omissions had statutory sanction and could not be considered as constituting a public nuisance in a legal sense. It may be granted at once that the ordinance of the board of health had the force of a statute, for the Greater New York Charter so provides. But this ordinance did not purport to prescribe nor to authorize any detail in the act of "pasteurization," such as was charged against the defendant in this proceeding. It did require "pasteurization" generally, but it is very far-fetched to think that this requirement authorized, much less directed, the making of unnecessary noises in the very early hours of morning, either within or without the defendant's plant, and to the great annoyance of the residents of the neighborhood. The defendant urged further that the judgment was reached by ignoring the necessity of proving a criminal intent on the part of the defendant, and that therefore it was based on a substantial error of law. What is meant by the phrase "criminal intent," within the scope of the definition of the crime of maintaining a public nuisance? It does not mean that one who is charged with the commission of that offense should be shown to have consciously and positively intended to interfere with the comfort and repose of "any considerable number of persons." His criminality is independent of any positive purpose of annoyance. It can arise as well from his very failure to think of anybody but himself, and, generally, public nuisances, whenever and wherever they exist, arise from just such self-concentration. The acts involved here were so continuous and persistent as to indicate on the part of the defendant's employees a complete indifference to the rights of others and, as to the crime now under consideration, to establish a "criminal intent" within the meaning of the law.

Injury to Previously Injured Person—Distinction Between Hypothetical and Other Questions

(Blake vs. City of Bedford (Ia.), 151 N. W. R. 74)

The Supreme Court of Iowa affirms a judgment for $2,750 in favor of the plaintiff, a man about 60 years old, who was injured on a defective sidewalk more than nine months after he had been injured by a fall from a ladder. The court says that the fact that the plaintiff had sustained a prior injury was of course material, but it constituted no defense to this action, if he succeeded in showing to the jury, that, by reason of the defendant's negligence with respect to its sidewalk, he was made to fall, without fault on his part, and thereby received other or additional or increased injury. A physician who was shown to have personally examined and treated the plaintiff for his injuries was asked for his opinion whether a union, bony or fibrous, of the broken bone had taken place prior to the plaintiff's fall on the sidewalk. In this question the witness was asked, among other things, to speak from his examination and observation of the patient. It was urged that the witness should not have been allowed to answer until he had first detailed to the jury all that he had learned or discovered in his examination and treatment of the patient. But such is not the rule. If a witness is testifying purely as an expert, pronouncing an opinion solely on a hypothetical state of facts, then of course it is the right of the opposing party to insist that the question shall disclose all the facts on which the opinion is to be pronounced. But, if the witness be a physician who professes to speak from his personal observation, examination, and treatment, he may properly express an opinion based thereon, it being, of course, the privilege of counsel on the other side, by cross-examination, to test its accuracy and reasonableness.

Information Not Obtained for Purpose of Treatment Is Not Privileged

(Cherpeski vs. Great Northern Railway Co. (Minn.), 150 N. W. R. 1091)

The Supreme Court of Minnesota, in reversing a judgment obtained by the plaintiff for personal injuries, holds that it was error to exclude the testimony of two physicians called as witnesses by the defendant. One of them was a physician and surgeon of the Northwestern Road. The defendant proposed showing that the plaintiff went to him and was examined for the purpose of ascertaining whether he could enter the service of the road. The other physician was the general surgeon of the defendant. The plaintiff, according to the offered proof, went to him to ascertain whether he was physically able to remain in the service of the company. In neither case was curative treatment contemplated. In neither case did the physician obtain information to enable him to prescribe or act for the plaintiff. Objections to the proposed testimony were sustained on the ground that the information sought was privileged. But from the showing made or offered to be made the court thinks it affirmatively appeared that the information obtained by the two physicians was not privileged. At common law communications between physician and patient or information obtained by the physician in treating his patient were not privileged. The privilege comes from the statute.

Injury from Negligently Cutting Through Bandage—Care Required in Public Dispensary

(Volkell vs. Wolf (N. Y.), 151 N. Y. Supp. 918)

The Supreme Court of New York, Appellate Term, First Department, which affirms a judgment in favor of the plaintiff, amount not stated, says that the defendant, a surgeon, operating in a dispensary, inflicted an injury on this infant plaintiff while cutting through a bandage in which the child's broken arm was wrapped. The defendant claimed that, if the bandage had been adjusted properly and in the usual fashion, the patient's hand would have been fastened tightly to the body and in no danger of being cut. He admitted that before cutting he made no examination to ascertain where the hand was, or what was concealed under the point where he applied the shears, claiming that "he had a right to assume that it (the bandage) was properly put on; also that, "I think the whole hand was exposed, but I did not see it; I had the impression that the bandage was outside of the upper part;" also that it was merely good fortune that the infant's hand was not cut off. The hurry of work in a public dispensary does not excuse the lack of ordinary care. The defendant could not assume that the hand was in a safe position, and rely on that, when the fact could be readily ascertained by himself before applying the shears. The finding of negligence was warranted by the evidence.

What Constitutes Removal of Hand at Wrist

(Moore vs. Aetna Life Insurance Co. (Ore.), 146 Pac. R. 151)

The Supreme Court of Oregon affirms a judgment for the plaintiff, where the question was disputed as to whether his hand had been removed at the wrist. The court says that the question was one of extreme nicety, and there is a dearth of decisions covering the exact point, there being no case cited by counsel or discovered by the court involving the construction of a policy exactly identical in its terms with the one on which this action was predicated. This was an action to recover on an accident insurance policy, which provided that the plaintiff should be entitled to recover $1,000 if he should suffer accidental injuries resulting in the "loss of a hand by removal at or above the wrist." The plaintiff was accidentally shot in the hand, necessitating the removal of all the bones of the hand at the wrist except the metacarpal bone of the thumb. From the medical testimony, which was meager, and photographs taken about the time of the trial, it appears that the amputation began at the inner side of

the left wrist, removing probably a small portion of the unciform bone, and including in the operation all the metacarpal bones of the four fingers at their articulation with the unciform, os magnum, and trapezoid, respectively. The os magnum, trapezoid, and trapezium were clearly left intact, and the bones of the thumb, while possibly injured by the shot, retained their continuity. The thumb itself was not removed, although the ball of that member was partially destroyed and the ligaments so injured that it was stiff and entirely useless. The medical witness stated that in his opinion it would have been better to have removed what remained of the thumb, so that the plaintiff could have had an artificial hand. There was enough of the flesh of the hand to cover the bones of the wrist, forming what the medical witness termed "a bunch of hardened callus" at the end of the wrist, probably no more than good surgery would require for the protection of the bones of the wrist. The court is of the opinion that the plaintiff was within the true meaning and spirit of the policy. He had a good hand against losing the use of which he desired to insure. If he had been told the intent and meaning of the policy was such that if in case of a necessary amputation the surgeon should leave some useless shred of his hand to be a source of annoyance and inconvenience, and thereby his policy would be practically worthless, does any sane person believe for a moment he would have taken out the policy? The substance of what he sought was insurance against the possible loss of his hand as a useful member of his body. Substantially he lost his hand by removal at the wrist.

AMERICAN GASTRO-ENTEROLOGICAL ASSOCIATION

Eighteenth Annual Meeting, held at Baltimore, May 10, 1915

The President, Dr. Joseph C. Bloodgood, in the Chair

Benign Growths of the Stomach

Dr. Seymour Basch, New York: Only the genuine new growths are considered. They include mucous polypi, adenomas, lymphadenomas, myomas, fibromas, lipomas, myxomas, osteomas and cysts. When the mucous membrane is not involved and there is no obstruction from the growth, normal conditions of the gastric secretion should prevail.

DISCUSSION

Dr. Jacob Kaufmann, New York: A patient whom I had occasion to see several times with her physician, a girl, suffered from her fourteenth to her nineteenth year with repeated gastric hemorrhages of very severe type, occurring shortly before menstruation. Roentgenograms made on two occasions showed the characteristic picture of penetrating ulcer of the duodenum. At operation, the duodenum and pyloric part of the stomach were found normal, but fibroma was discovered at its cardiac end. The mucous membrane around it was quite congested, and when the tumor was handled, a profuse hemorrhage was produced. I think we have every reason to pronounce this a true case of menstrual bleeding from the stomach.

Dr. Henry W. Bettmann, Cincinnati: A man, now about 50 years of age, has suffered for fifteen years with pain and hyperacidity of the stomach. Nine years ago, an operation was done, and the whole mucous membrane was found covered with small polyadenomas. We did nothing but sew up the stomach again. He will probably go on for the rest of his life suffering from the same symptoms. The supposed rarity of these cases may be due to the fact that we have failed to put isolated cases of this character on record.

Dr. John A. Lichty, Pittsburgh: I should like to ask Dr. Basch whether he relies largely on the Roentgen ray in making the diagnosis. The slides he has exhibited seem to show a rather large shadow. In cases of small polypi, however, I can hardly see how the Roentgen ray would help.

Dr. Seymour Basch, New York: The Roentgen ray is a distinct advance in the diagnosis of borderline cases. Roentgenograms show not only a distinct shadow defect caused by the penetration of the tumor into the bismuth, but also a notched appearance.

The Cause of the Variations in the Gastric Hunger Contractions with Age

Dr. T. L. Patterson, Baltimore: By starving young and old animals, it is possible to show that in very young dogs the contractions of the empty stomach are practically continuous, while in old animals there is a decrease in the gastric hunger activity proportional to the advance in age. Gastric hunger variations appear in the gastric tonus, in the strength and rapidity of the hunger contractions, and especially in the duration of the hunger and quiescence periods of the stomach, the cause of which is produced by two differentiated factors, namely, age and rate of metabolism. The gastroneuromuscular apparatus is independent of the central nervous system. In prolonged starvation, the hunger sensation may be lost, while the hunger contractions persist.

DISCUSSION

Dr. Ludwig W. Kast, New York: Is there any relation between the hunger contractions and the gastric secretion?

Dr. Joseph C. Bloodgood, Baltimore: In these experiments, did Dr. Patterson differentiate between the different groups by restricting all food and liquid in one group, and restricting food alone in the other? If so, I should like to know whether there was any difference in the contractions when the animals had all the water they wanted.

Dr. T. L. Patterson, Baltimore: Regarding the relation between the gastric hunger contractions and the gastric secretion, anything that comes in contact with the gastric mucosa will inhibit the gastric hunger contractions at once whether it be water or food. The hunger contractions do not seem to have much effect on the gastric secretion. All the animals had free access to water, but had no food.

The Effect of Certain Gastric Conditions on the Salivary Secretion

Dr. T. R. Brown, Baltimore: Our studies show that the chewing of bland substances produces a considerable flow of saliva, which is quite rich in diastatic ferment. A comparison of normal cases with cases in which there was increased, diminished or absent hydrochloric acid showed that there were no variations from the normal in respect to quantity, alkalinity or diastatic ferment content of the saliva sufficiently great to make us feel that there is any definite relationship between the character of the gastric juice and that of the saliva. It does not appear probable that quantitative or ferment changes in the saliva play any considerable part in the development of the glossitis, gingivitis or stomatitis, so frequently met in a case of achylia gastrica.

Dr. E. B. Freeman, Baltimore: In one of our cases of achylia due to carcinoma of the stomach, the diastase test was positive, and also in a case of hyperacidity, there being a large amount of diastase present in both cases.

the surrounding skin in relation to the condition of the colon before the operation. If it has been diseased to such an extent that the ileum has taken up the function of the colon, we may find no irritation and normal stools, as in this case. When, however, the ileum is functionating normally, we may have trouble, as in my last case.

Dr. J. M. Lynch, New York: I have never performed an ileostomy on a person with a practically healthy colon, so I cannot say how its contents would flow from the ileum in these circumstances. I do not know that we ever have polyposis with a simple or catarrhal inflammation. I believe that the polyposis is secondary to the inflammation.

Study of Carbohydrate Cures in Diabetes Mellitus

Dr. John C. Hemmeter, Baltimore: Diabetes mellitus is a disease the pathogenesis of which has involved every organ of the body except the heart and lungs, and the chief cause of which is an affection of the islands of Langerhans in the pancreas. My personal observations were made under quantitative controls of the blood, stools and urine. The method for determining the amount of sugar in the blood is one within the reach of every general practitioner. It is the Ivar Bangs method of quantitative estimation. We must differentiate between the disappearance of sugar from the urine and increased carbohydrate tolerance. A human being cannot live without sugar, so we cannot entirely withhold it; but we can give a kind that is not converted into glycogen, but goes into the circulation direct, such as the oatmeal inosit and hediosit sugar.

DISCUSSION

Dr. John A. Lichty, Pittsburgh: So far as the method of Bangs is concerned, I do not believe that it will help us clinically until there has been further study. There must be more sugar at some times during the day than at others, according to the times of taking food and taking exercise. I did not see much difference in the patients to whom I fed hediosit. I have recently tried Allen's method of treatment in nine cases with very good results.

Dr. Max Einhorn, New York: In some cases, which I have studied, the ferments may be normal; in some, there is hypersecceretion of the pancreas; and in others, there is too little secretion. The external secretion may be changed in different ways.

Dr. Charles O. Stockton, Buffalo: There is no doubt that in the majority of severe cases, the patients may be made sugar-free, and even free from the presence of acetone bodies in the urine, by this method; and that we may establish a higher and higher carbohydrate balance; but occasionally we find a patient in whom we cannot raise the carbohydrate tolerance above about 30 gm., and who may easily lose even that. These unsuitable cases will do better on certain forms of carbohydrate than on others.

Dr. Ludwig W. Kast, New York: What the general practitioner wants to know is how much of all these studies in regard to these different forms of carbohydrate lends itself to direct practical application.

Dr. John C. Hemmeter, Baltimore: You must try to increase the weight of the patient, without trying to get him sugar-free. A little sugar does not matter, if his carbohydrate tolerance is increasing. After this treatment, which has an effect on the islands of Langerhans, the patient can stand bread and starch better.

The Value of Rectal Alimentation

Dr. Harry Adler, Baltimore: The usual method of rectal feeding is unsatisfactory. The drop (Murphy) method, with peptonized milk and sugar solution, is markedly less annoying. In our experiments, the largest amount of nitrogen that we were able to supply daily was 8.9 gm., of which 8.06 gm. was returned with the stools. According to the observations of Dr. Muller, the stools of individuals taking absolutely no nourishment contain 0.2 gm. per diem. With this deducted from our estimations of the returned nitrogen, we have in no case observed an absorption of more than 50 per cent. of the protein supplied; and it has fallen to as low as 30 per cent. The average amount of nitrogen absorbed in these cases was 1.14 gm. per diem. When we compare the amount of nitrogen lost by these cases with the amount that it was possible for them to absorb by colonic feeding, we realize how little we can accomplish. The difference between nutritional enteroclysis and normal salt enteroclysis is little over one-tenth of the tissue albumin loss per diem; over the periods of time that rectal feeding is usually carried out, it is, from a practical standpoint, an almost negligible quantity.

DISCUSSION

Dr. Jacob Kaufmann, New York: Some of the nitrogen found in the stools is derived from the secretions, and this constitutes a possible source of error in making the estimations. I do not think that there is absolute proof of the uselessness of nutrient enemas.

Dr. Max Einhorn, New York: We should try to give glucose by rectum, as it is the best material.

Dr. Franklin W. White, Boston: I think it is valuable to contrast with this piece of work done by Dr. Adler the fact that nitrogenous equilibrium can be maintained by duodenal feeding. You can get it all in by the duodenum, but not by the rectum.

Dr. Louis M. Gompertz, New Haven, Conn.: In some experiments that we conducted, a few years ago, it was found that the rectum is capable of salt absorption to about the same degree as the stomach. Experiments were also made with various other solutions. While I believe rectal feeding to be a pure makeshift, half a loaf is better than none. The use of salt solutions, water and dextrose solutions will tide the patients over the critical period required for rectal feeding.

Dr. John C. Hemmeter, Baltimore: I should like to know whether the calculation that you can supply only one-tenth of the nitrogen required by colonic feeding was based on the metabolism experiments made during rest or during activity. During rest, the food taken is entirely used in keeping up the heat of the body, which can be done without food, by artificial means.

Dr. Harry Adler, Baltimore: The patients were absolutely at rest, in bed, or they could not have been fed by the drop method. We could supply only one-tenth of the amount needed when at rest. It is impossible to estimate accurately the absorption of sugar. We cannot give large amounts of milk by the drop method, because the rectum soon becomes irritated. We gave 8 ounces at a feeding, and gave three feedings a day.

Duodenal Ulcer with Especial Reference to Its Roentgen-Ray Diagnosis

Dr. R. Walter Mills, St. Louis: The object of the paper is to review certain clinical findings in duodenal ulcer in their relation to clinical teaching and experience. The observations are founded on a series of thirty operatively confirmed cases of duodenal ulcer and eighty cases so diagnosed and treated medically, in which both clinical and Roentgen-ray findings were characteristic of duodenal ulcer, including six with a history of hemorrhage. We may conclude that the greater efficiency of controlling alkalies in duodenal ulcer as compared with gastric ulcer is due to the small amount of stomach and duodenal contents present at the time; that pylorospasm has nothing to do with causing the pain of duodenal ulcer; that the pain must originate in the cap; that all indications are unfavorable to the idea that the pain of duodenal ulcer is due to hypertension, the so-called adequate stimulus of visceral pain, but is in favor of the idea that the nerve-endings in the ulcer floor become abnormally sensitive to an excess of hydrochloric acid.

The Roentgen Ray in Gastro-Intestinal Affections

Dr. Charles D. Aaron, Detroit: I wish to make a plea for a standard Roentgen-ray test meal. I am of the opinion that the adoption of the following suggestions will increase the value of the Roentgen ray as a diagnostic aid in gastro-enterology: The roentgenologist should be a trained and experienced anatomist and pathologist. There should be standardization of methods and technic. The physician should acquire the ability to make a probable estimation of

DISCUSSION

Dr. G. C. Mizell, Atlanta, Ga.: It has seemed to me that during the last five years there has been a marked increase in the number of cases of hyperchlorhydria and achylia gastrica in patients in the South presenting themselves for treatment of gastro-intestinal disturbance. I have not found any relationship between the gastric and the salivary secretion. I have tested for the ferments, and have not found them absent in any of the cases.

Dr. Max Einhorn, New York: I think that achylia gastrica is more frequent in patients coming from the South than in Northerners, but cannot say whether it is on the increase. In fact, it would not be easy to tell, because formerly we did not know much about achylia.

Dr. John A. Lichty, Pittsburgh: I have always been accustomed to attribute the dryness of the mouth and the glossitis that we usually find in cases of achylia gastrica to that condition. I have found that patients with malignant disease of the stomach complain frequently of an increase of saliva. I have recently come to the conclusion that this occurs only in those cases of carcinoma in which the growth is near the esophageal opening.

Dr. Jacob Kaufmann, New York: The difficulty I have found is in examining the saliva, which is a very complicated secretion. It is composed of secretions of different glands. It is a question whether, in examining the saliva, it is sufficient to examine for alkalinity and different ferments.

Dr. Ludwig W. Kast, New York: There are two points that interested me particularly. One is the fact that mechanical stimulation of the salivation brings about secretion from the parotids. The other point is the relationship between the nutritive or inflammatory changes in the tongue and the mucous membrane of the mouth and conditions of the stomach. Achylia gastrica may be secondary to disturbances in the mouth.

Dr. Charles D. Aaron, Detroit: In cases of pernicious anemia in which there is achylia gastrica, we usually find a glossitis. The subsidence of glossitis with the giving of hydrochloric acid leads one to believe that there is some connection between the stomach and the trouble in the mouth.

Dr. Joseph C. Bloodgood, Baltimore: During the last year I have been especially interested in a group of cases in which the tongue showed a peculiar lesion that I was at first afraid might be cancer. Of 100 cases of cancer of the tongue, however, only three were in women; but this lesion seems to be just as frequent in women as in men. It is often associated with achylia. It occurs in the middle of the tongue, from base to tip; but I have never seen cancer, except at the tip.

Dr. E. B. Freeman, Baltimore: In both cases, the carcinoma was along the lesser curvature, and probably primary.

Dr. T. R. Brown, Baltimore: We had the patient chew a piece of rubber tubing of definite size for twenty minutes, and this brought about secretion. I am quite sure that glossitis and gingivitis are more prevalent in benign than in malignant achylia. The hyperacidities and the achylias showed about the same degree of secretion. I do not believe that there is much relation between gastric and salivary secretion, but it is probable that there is a relation between the salivary and the pancreatic.

Recent Studies in Pancreatic Secretion

Dr. Max Einhorn, New York: I have examined a number of normal persons by means of the agar-tube method, in order to find the standard content of amylopsin, steapsin and trypsin in the pancreatic juice. Boiled milk and unboiled milk were used in examining both the gastric and the pancreatic secretions. Each ferment should be examined separately, because if one ferment is found high, the others are not always high in proportion. By the amount of change found in the tube after twenty hours, one can estimate approximately the amount of the ferment examined that is present.

DISCUSSION

Dr. T. R. Brown, Baltimore: An interesting point is the variation in the amount of the different ferments according to the pabulum given.

Dr. Franklin W. White, Boston: It seems to me that some of the variation in the amount of the three ferments may be due to the technic of the ferment test, which is certainly not simple or altogether satisfactory. I think the proteolytic ferment, the trypsin, is more valuable for diagnostic purposes than either the amylase or the lipase.

Dr. Jacob Kaufmann, New York: Usually these examinations are made with the patient in a fasting condition. It is a question whether, if the tube is introduced into the duodenum before the meal is given, it gives one an opportunity to tell how the pancreas secretes.

Dr. Clement R. Jones, Pittsburgh: In a case in which the feces contained large fermented curds, this seemed to me to demonstrate a lack of balance between the pancreatic and other intestinal secretions. The condition was controlled by administering sodium citrate in the milk, thus splitting up the curds.

Dr. Max Einhorn, New York: The tubes spoil after being kept more than two or three months; but if kept on ice, they last very well for five or six weeks. I have made the examinations with the patients in a fasting condition or after taking tea and sugar. If solid food is given, the tube will block up; but any liquid food may be given. The results obtained in a fasting condition were the same as those after taking tea and sugar.

Surgical Physiology of the Colon

Dr. William Draper, New York: The influence of heredity and environment on the functional abnormalities of the human colon is great, and these fundamental biologic factors are worthy of further consideration. To attribute pathologic conditions of the colon to any single factor is a grave error, as isolated deficiencies may be compensated for. Many complicated factors go to maintain the balance. No matter how severe the derangement within the bowel, so long as balance is maintained, the body is protected. When the defensive power is weakened, the symptoms immediately arise.

DISCUSSION

Dr. Treby Lyon, New York: From personal experience, I can say that after solidification of the feces, which occurs in six weeks, there is so little discomfort after ileostomy compared with the relief afforded by the cessation of the symptoms that I should unhesitatingly advise its employment in severe cases of inflammation of the colon.

Dr. J. M. Lynch, New York: Dr. Lyon came under my care three years ago, suffering from diarrhea alternating with constipation, loss of weight, and the passage of blood and mucus. The methods of treatment previously tried by him had proved of little use, and I suggested treating the polyposis, which is usually associated with inflammation of the colon, by putting the colon at rest by means of complete ileostomy, which was done. In seven other cases as well the patients had free movements after a short time. There is perhaps a little more discomfort from an ileostomy than from a colostomy, but very little; and all the patients had gained in weight. Dr. Lyon practices his profession, and very few people in his town know that he has an opening in his side. There are no tumors remaining now, so far as we can see.

Dr. J. C. Bloodgood, Baltimore: I think we have had a pretty good demonstration that side-tracking of the colon with an artificial anus near the cecum is by no means an unbearable condition.

Dr. Seymour Basch, New York: Was the inflammation in Dr. Lynch's cases primary, and the polyposis secondary, or was it an infectious process?

Dr. Willy Meyer, New York: Was the colon side-tracked for the purpose of avoiding the irritation from the feces or for the sake of irrigation of the colon? It is important for physicians and surgeons to find out whether this radical treatment is always necessary.

Dr. Joseph C. Bloodgood, Baltimore: When we side-track the colon by bringing out the ileum, there will be a difference in the irritative character of the effect of the fecal flow on the surrounding skin in relation to the condition of the colon before the operation. If it has been diseased to such an extent that the ileum has taken up the function of the colon, we may find no irritation and normal stools, as in this case. When, however, the ileum is functionating normally, we may have trouble, as in my last case.

DR. J. M. LYNCH, New York: I have never performed an ileostomy on a person with a practically healthy colon, so I cannot say how its contents would flow from the ileum in these circumstances. I do not know that we ever have polyposis with a simple or catarrhal inflammation. I believe that the polyposis is secondary to the inflammation.

Study of Carbohydrate Cures in Diabetes Mellitus

DR. JOHN C. HEMMETER, Baltimore: Diabetes mellitus is a disease the pathogenesis of which has involved every organ of the body except the heart and lungs, and the chief cause of which is an affection of the islands of Langerhans in the pancreas. My personal observations were made under quantitative controls of the blood, stools and urine. The method for determining the amount of sugar in the blood is one within the reach of every general practitioner. It is the Ivar Bangs method of quantitative estimation. We must differentiate between the disappearance of sugar from the urine and increased carbohydrate tolerance. A human being cannot live without sugar, so we cannot entirely withhold it; but we can give a kind that is not converted into glycogen, but goes into the circulation direct, such as the oatmeal inosit and hediosit sugar.

DISCUSSION

DR. JOHN A. LICHTY, Pittsburgh: So far as the method of Bangs is concerned, I do not believe that it will help us clinically until there has been further study. There must be more sugar at some times during the day than at others, according to the times of taking food and taking exercise. I did not see much difference in the patients to whom I fed hediosit. I have recently tried Allen's method of treatment in nine cases with very good results.

DR. MAX EINHORN, New York: In some cases, which I have studied, the ferments may be normal; in some, there is hyperseceretion of the pancreas; and in others, there is too little secretion. The external secretion may be changed in different ways.

DR. CHARLES O. STOCKTON, Buffalo: There is no doubt that in the majority of severe cases, the patients may be made sugar-free, and even free from the presence of acetone bodies in the urine, by this method; and that we may establish a higher and higher carbohydrate balance; but occasionally we find a patient in whom we cannot raise the carbohydrate tolerance above about 30 gm., and who may easily lose even that. These unsuitable cases will do better on certain forms of carbohydrate than on others.

DR. LUDWIG W. KAST, New York: What the general practitioner wants to know is how much of all these studies in regard to these different forms of carbohydrate lends itself to direct practical application.

DR. JOHN C. HEMMETER, Baltimore: You must try to increase the weight of the patient, without trying to get him sugar-free. A little sugar does not matter, if his carbohydrate tolerance is increasing. After this treatment, which has an effect on the islands of Langerhans, the patient can stand bread and starch better.

The Value of Rectal Alimentation

DR. HARRY ADLER, Baltimore: The usual method of rectal feeding is unsatisfactory. The drop (Murphy) method, with peptonized milk and sugar solution, is markedly less annoying. In our experiments, the largest amount of nitrogen that we were able to supply daily was 8.9 gm., of which 8.06 gm. was returned with the stools. According to the observations of Dr. Muller, the stools of individuals taking absolutely no nourishment contain 0.2 gm. per diem. With this deducted from our estimations of the returned nitrogen, we have in no case observed an absorption of more than 50 per cent. of the protein supplied; and it has fallen to as low as 30 per cent. The average amount of nitrogen absorbed in these cases was 1.14 gm. per diem. The difference between nutritional enteroclysis and normal salt enteroclysis is little over one-tenth of the tissue albumin loss per diem; over the periods of time that rectal feeding is usually carried out, it is, from a practical standpoint, an almost negligible quantity.

DISCUSSION

DR. JACOB KAUFMANN, New York: Some of the nitrogen found in the stools is derived from the secretions, and this constitutes a possible source of error in making the estimations. I do not think that there is absolute proof of the uselessness of nutrient enemas.

DR. MAX EINHORN, New York: We should try to give glucose by rectum, as it is the best material.

DR. FRANKLIN W. WHITE, Boston: I think it is valuable to contrast with this piece of work done by Dr. Adler the fact that nitrogenous equilibrium can be maintained by duodenal feeding. You can get it all in by the duodenum, but not by the rectum.

DR. LOUIS M. GOMPERTZ, New Haven, Conn.: In some experiments that we conducted, a few years ago, it was found that the rectum is capable of salt absorption to about the same degree as the stomach. Experiments were also made with various other solutions. While I believe rectal feeding to be a pure makeshift, half a loaf is better than none. The use of salt solutions, water and dextrose solutions will tide the patients over the critical period required for rectal feeding.

DR. JOHN C. HEMMETER, Baltimore: I should like to know whether the calculation that you can supply only one-tenth of the nitrogen required by colonic feeding was based on the metabolism experiments made during rest or during activity. During rest, the food taken is entirely used in keeping up the heat of the body, which can be done without food, by artificial means.

DR. HARRY ADLER, Baltimore: The patients were absolutely at rest, in bed, or they could not have been fed by the drop method. We could supply only one-tenth of the amount needed when at rest. It is impossible to estimate accurately the absorption of sugar. We cannot give large amounts of milk by the drop method, because the rectum soon becomes irritated. We gave 8 ounces at a feeding, and gave three feedings a day.

Duodenal Ulcer with Especial Reference to Its Roentgen-Ray Diagnosis

DR. R. WALTER MILLS, St. Louis: The object of the paper is to review certain clinical findings in duodenal ulcer in their relation to clinical teaching and experience. The observations are founded on a series of thirty operatively confirmed cases of duodenal ulcer and eighty cases so diagnosed and treated medically, in which both clinical and Roentgen-ray findings were characteristic of duodenal ulcer, including six with a history of hemorrhage. We may conclude that the greater efficiency of controlling alkalies in duodenal ulcer as compared with gastric ulcer is due to the small amount of stomach and duodenal contents present at the time; that pylorospasm has nothing to do with causing the pain of duodenal ulcer; that the pain must originate in the cap; that all indications are unfavorable to the idea that the pain of duodenal ulcer is due to hypertension, the so-called adequate stimulus of visceral pain, but is in favor of the idea that the nerve-endings in the ulcer floor become abnormally sensitive to an excess of hydrochloric acid.

The Roentgen Ray in Gastro-Intestinal Affections

DR. CHARLES D. AARON, Detroit: I wish to make a plea for a standard Roentgen-ray test meal. I am of the opinion that the adoption of the following suggestions will increase the value of the Roentgen ray as a diagnostic aid in gastroenterology: The roentgenologist should be a trained and experienced anatomist and pathologist. There should be standardization of methods and technic. The physician should acquire the ability to make a probable estimation of the diagnostic value of a Roentgen-ray report. The patient should not be subjected to operation without a confirmation of the original findings by a second Roentgen examination, made after an interval of two or three days. The clinician must not attach too much significance to the Roentgen-ray findings, unless they are absolutely decisive. The lesion discovered by the Roentgen ray must be a constant finding, regardless of position or slight variations in technic. Great care must be exercised to differentiate physiologic and spastic conditions from those that are essentially pathologic. The Roentgen-ray report should be considered on the same basis as any laboratory report. The physician must carefully correlate the Roentgen-ray findings with the anamnesis and the clinical and laboratory findings.

DISCUSSION

Dr. F. H. Baetjer, Baltimore: With different meals, the motility and emptying time of the stomach are different; so that it is impossible to reconcile the findings of one roentgenologist with another. Every stomach is different, so you must determine the motility from the standpoint of that individual stomach. For instance, the stomach of a fat man occupies a horizontal position, and tends to empty more quickly than the fish-hook stomach found in a thinner person. Moreover, chronic irritative lesions elsewhere in the digestive tract will produce changes in the gastric condition.

Dr. Arthur F. Chase, New York: In making a diagnosis, it is important to realize that the patients are laboring under a peculiar nervous condition with this enormous amount of bismuth in the stomach. Prolonged examinations, therefore, will produce abnormal pictures. I believe the pain in duodenal ulcer to be due to spasm produced by substances passing over irritated nerves.

Dr. George R. Lockwood, New York: While Roentgen-ray diagnosis has been one of the most valuable things in internal medicine brought into use within the last few years, it has its limitations. When it agrees with clinical and laboratory findings, we are quite correct in thinking we have done a good thing in making Roentgen-ray examination; but when the Roentgen-ray diagnosis is not corroborated or is antagonized by other clinical laboratory methods, we are decidedly puzzled.

Dr. Clement R. Jones, Pittsburgh: I wish to enter a protest against the use of buttermilk as a vehicle for the bismuth. The varying degrees of acidity of commercial buttermilk may account for some of the variations in the results at different times.

Dr. Fred B. Lund, Boston: I have seen several cases lately in which the diagnosis of duodenal ulcer was made on the basis of deformities in the duodenal cap, but in which operation showed adhesions of the great omentum to the pylorus or to scars on the abdominal wall, producing an S-shape to the duodenum, and even the appearance of a little cap. The long, narrow line that Dr. Mills says is indicative of cancer may prove a valuable aid in early diagnosis. It was seen in two cases of growth of the pylorus which I had recently. I had supposed it occurred only in cases of extensive cancer, but both these growths were simply on the side of the pylorus and the first portion of the duodenum.

Dr. Willy Meyer, New York: It is wrong to let cases go to the Roentgen-ray man without giving him their clinical history, and then ask him to make a report on which to base a diagnosis, as is done in most hospitals.

Dr. Dudley D. Roberts, Brooklyn: Perforating gastric ulcers are rather uncommon. I have seen only two perfect pictures of this condition among my own cases, one with, and the other without an air-bubble. Both refused operation, were treated medically, and made an entire symptomatic recovery.

Duodenal Feeding in Atony, Dilatation and Ptosis of the Stomach

Dr. Clement R. Jones, Pittsburgh: The duodenal tube as used by Dr. Einhorn has been of exceptional service in selected cases. It is the ideal method of rest for the stomach, at the same time supplying the body with nutritious food at a point in the intestinal tract where it can be digested. Certain points in the modification of the treatment suggested by Dr. Morgan have served to place the treatment on a very practical basis: (1) the longer tube, which allows the food to enter the intestines at a point where it can exert no direct pressure on a duodenal ulcer; (2) the discontinuation of the use of sugar of milk in some cases; (3) the drop by drop method, by which it is possible to keep up a continuous flow of the nutrient fluid. In addition, various slight changes in the technic must be made from time to time by those prescribing this treatment.

DISCUSSION

Dr. Julius Friedenwald, Baltimore: I have used the duodenal tube a great deal in the feeding of cases of ulcer that have resisted the usual method of feeding, and in cases of persistent vomiting, and am quite convinced that I have saved lives by this means.

Dr. Franklin W. White, Boston: I have been impressed with the results of the use of this method in my practice, even when the tube had to be sent out to the country to be used by a doctor there. It deserves more thorough trial than it is getting at present.

Dr. Willy Meyer, New York: My experience with the tube is limited to cases of ulcer. I am opposed to its use in atony.

Dr. Max Einhorn, New York: I have never had any case of perforation from the use of the tube. It usually goes down to a point 8 cm. from the teeth, but it can go as far as 92. The pylorus is 56 cm. from the teeth. I have seen some cases of atony and ptosis in which, after two weeks of this treatment, there was a change in the shape and position of the stomach.

Dr. Thomas Charles Martin, Washington, D. C.: The distance from the incisors to the cardia in a given case is the same as the distance from the eye to the elbow; and that from the cardia to the duodenum is equal to the longest diameter of the splash sound area when the patient is in an angle of 15 degrees.

3. Use and Abuse of Pituitary Extract in Obstetrics.—Norris would never use this without exhausting his abilities in obstetric diagnosis. He considers that healthy multiparas with relaxed birth canals offer the widest and safest fields. For inertia in the early stage of labor, the sleep of morphin, chloral or scopolamin is preferred; in the advanced stages of labor, pituitary extract, he says, often will wisely keep forceps innocuous. The uterus, after the tumultuous visitation of pituitary extract, usually needs the steadying hand of ergot. Half doses are more often to be employed than full doses.

4. **Method of Closing Abdominal Incision.**—With the method used by Heineberg, cutting of the skin and the introduction of infection from the cutaneous surface by the silkworm-gut sutures is avoided. It is performed as follows: The peritoneum is closed with a continuous suture of plain catgut. Silkworm-gut sutures are then introduced about 1 inch apart at the edge of the incision just beneath the skin surface and include all of the layers of the abdominal wall except the peritoneum. The point of emergence of the suture on one side of the incision must be exactly opposite the point of entrance on the other. Each end of the suture is temporarily held in a hemostatic forceps. The deep fascia or aponeurosis is closed with a chromic-catgut suture, continuous or interrupted. The edges may be made to overlap if desired. The skin edges are apposed by a subcuticular stitch of plain catgut. The ends of the silkworm-gut sutures are then crossed and tied over a strip of iodoform gauze.

5. **Suturing in Amputation of Cervix.**—The following method of suture has been devised and employed by Heineberg with gratifying results. He says it is particularly applied to the single flap and circular amputations and the operation of tracheloplasty described by Bonney, but may also be employed in the double flap amputation. The advantages claimed for it are the accurate approximation of the edges of the flaps with a minimum degree of tension on the sutures. In suturing the flaps after a single flap amputation or tracheloplasty proceed as follows: A chromic catgut suture, the traction suture, is armed at each end with a well curved needle. Each needle is passed through the flap about ¼ inch from its edge; the points of introduction are on the raw surface of the flap ⅛ inch on each side of the median line and the points of emergence are on the vaginal or outer surface of the flap. Both needles are then introduced through the base of the flap at the junction of the raw surface and the mucous membrane of the cervical canal. They are passed through the entire thickness of the lip of the cervix and made to emerge on the vaginal surface about ¾ inch above the edge of the flap and ¼ inch apart. After sufficient traction has been applied to the ends of the suture to invert the flap and bring its edge and base into accurate apposition (avoiding unnecessary tension) the ends of the suture are tied to each other. The other lip is sutured in the same way. The two lips of the cervix which have been separated by the amputation, are drawn together by a mattress suture placed in each side of the cervix about ¼ inch external to the canal. This suture begins in the vaginal surface of the anterior lip about ½ inch above the edge of the flap and emerges on the raw surface of the flap near its base; it is then passed through the lower lip from the raw to the vaginal surface. In a like manner it is passed back through both lips on a line ¼ inch external to the first one. When the two ends of this suture are tied to each other the tension should be sufficient to insure hemostasis and approximation of the edges of the lips. These edges are then held in accurate apposition by interrupted sutures which should be superficially placed and firmly, but not tightly tied.

37. **Allen Treatment of Diabetes.**—Eight patients were treated by Hill and Sherrick on the Allen starvation plan. In every case the patient has become sugar-free and has stayed so, on a reasonable diet which enabled him to hold his weight. Some of these were severe cases of diabetes, young people treated before by the old method and who could not be made sugar-free. When the patient is discharged from the ward he is given written diet slips with two or three menus which he can use on different days, figured out carefully to correspond with his tolerance. The two most important things to remember in this treatment are the following: First, do not raise the diet too quickly after starvation, and pay just as much attention to the protein intake as to the carbohydrate. Second, do not worry if the patient loses weight; it will not hurt him.

There has been no sign of coma in the eight cases treated. The ammonia has always been low, only in one case reading as high as 2.5 gm. per day, which is not at all a high ammonia. In most of the cases it has been very low, usually under a gram a day. This very possibly is due to the low protein intake. There was nothing constant in the appearance or disappearance of the acetone and diacetic acid while on starvation. In one case both disappeared, in others they increased slightly and in others stayed practically the same. No patient has lost more than 5 pounds during his treatment and no patient has gained more than 7 pounds. In most of the cases the weight at discharge was practically the same as at entrance.

the diagnostic value of a Roentgen-ray report. The patient should not be subjected to operation without a confirmation of the original findings by a second Roentgen examination, made after an interval of two or three days. The clinician must not attach too much significance to the Roentgen-ray findings, unless they are absolutely decisive. The lesion discovered by the Roentgen ray must be a constant finding, regardless of position or slight variations in technic. Great care must be exercised to differentiate physiologic and spastic conditions from those that are essentially pathologic. The Roentgen-ray report should be considered on the same basis as any laboratory report. The physician must carefully correlate the Roentgen-ray findings with the anamnesis and the clinical and laboratory findings.

DISCUSSION

Dr. F. H. Baetjer, Baltimore: With different meals, the motility and emptying time of the stomach are different; so that it is impossible to reconcile the findings of one roentgenologist with another. Every stomach is different, so you must determine the motility from the standpoint of that individual stomach. For instance, the stomach of a fat man occupies a horizontal position, and tends to empty more quickly than the fish-hook stomach found in a thinner person. Moreover, chronic irritative lesions elsewhere in the digestive tract will produce changes in the gastric condition.

Dr. Arthur F. Chase, New York: In making a diagnosis, it is important to realize that the patients are laboring under a peculiar nervous condition with this enormous amount of bismuth in the stomach. Prolonged examinations, therefore, will produce abnormal pictures. I believe the pain in duodenal ulcer to be due to spasm produced by substances passing over irritated nerves.

Dr. George R. Lockwood, New York: While Roentgen-ray diagnosis has been one of the most valuable things in internal medicine brought into use within the last few years, it has its limitations. When it agrees with clinical and laboratory findings, we are quite correct in thinking we have done a good thing in making Roentgen-ray examination; but when the Roentgen-ray diagnosis is not corroborated or is antagonized by other clinical laboratory methods, we are decidedly puzzled.

Dr. Clement R. Jones, Pittsburgh: I wish to enter a protest against the use of buttermilk as a vehicle for the bismuth. The varying degrees of acidity of commercial buttermilk may account for some of the variations in the results at different times.

Dr. Fred B. Lund, Boston: I have seen several cases lately in which the diagnosis of duodenal ulcer was made on the basis of deformities in the duodenal cap, but in which operation showed adhesions of the great omentum to the pylorus or to scars on the abdominal wall, producing an S-shape to the duodenum, and even the appearance of a little cap. The long, narrow line that Dr. Mills says is indicative of cancer may prove a valuable aid in early diagnosis. It was seen in two cases of growth of the pylorus which I had recently. I had supposed it occurred only in cases of extensive cancer, but both these growths were simply on the side of the pylorus and the first portion of the duodenum.

Dr. Willy Meyer, New York: It is wrong to let cases go to the Roentgen-ray man without giving him their clinical history, and then ask him to make a report on which to base a diagnosis, as is done in most hospitals.

Dr. Dudley D. Roberts, Brooklyn: Perforating gastric ulcers are rather uncommon. I have seen only two perfect pictures of this condition among my own cases, one with, and the other without an air-bubble. Both refused operation, were treated medically, and made an entire symptomatic recovery.

Duodenal Feeding in Atony, Dilatation and Ptosis of the Stomach

Dr. Clement R. Jones, Pittsburgh: The duodenal tube as used by Dr. Einhorn has been of exceptional service in selected cases. 40. **Treatment of Peptic Ulcer.**—A critical study of the literature of the medical treatment of peptic ulcer, particularly the rest and diet cures, Blumer says, suggests certain conclusions. It seems safe to assume that certain types of peptic ulcer show a strong natural tendency to heal if given a fair chance. Ulcers near the pylorus tend to heal badly, while bleeding ulcers, for reasons not entirely clear, seem to heal unusually well. Many ulcers would doubtless heal on the all-important complete rest, plus any of the dietary regimens that have been discussed. Others would equally certainly fail to heal under any form of medical treatment. Originators of diets are apt to adhere too closely to those iets, and tend to become prejudiced against different, but equally efficacious ones. The practitioner, whose sole purpose is to cure his patients, and who need not be distracted from this by attempts to glorify the products of his own cortical cells, should realize that there are good points in all of the diets presented. Each has its advantages and each its drawbacks, and the wise physician is he who will use them as frameworks to be clothed with a dietary structure suitable to the needs of each individual patient.

43. **Diagnosis of Mediastinitis.**—Tuberculosis, Howard found, plays a very important rôle in the etiology of chronic mediastinitis. One or more of the pressure phenomena of mediastinal tumor and aortic aneurysm may be present in this condition. Perez' mediastinal friction was present in two of Howard's cases, and he suggests that it may prove of diagnostic value.

45. **Influence of Dieting on Course of Cancer.**—In the underfed host, as shown by special experiments, Rous found that proliferative processes take place slowly. Wounds require a long time to heal and an inert foreign body, such as agar-agar, is only tardily organized. It is easy to see why the development of tumors dependent on a supporting stroma would be slower in such animals.

47. **Causes of Indigestion.**—In order to determine the proportionate frequency of the various causes of indigestion, Vanderhoof tabulated the clinical diagnosis in a series of 1,000 patients examined by Hutcheson and himself. Appendicitis and cholecystitis were responsible for approximately 35 per cent. of the cases of chronic or recurring indigestion; peptic ulcer and neuroses, each 10 per cent., and carcinoma involving the stomach or bowels, 5 per cent. Ten per cent. of the cases fall into a group including chronic gastritis, visceroptosis, peritoneal adhesions, enterospasm and enterogenous toxemia; while 25 per cent. are included in a group in which the indigestion is a reflex disturbance from affections of the kidneys, lungs, heart, eyes, blood and ductless glands, ears, central nervous system, female pelvic organs, and migraine and chronic infectious diseases. The remaining 5 per cent. classified as miscellaneous, include such conditions as pellagra (eight cases), amebic dysentery (six cases), malaria (five cases), diseased tonsils and cyclic vomiting (in children, respectively, six and five cases), intestinal parasites (four cases), together with instances of diverticulitis, peritoneal tuberculosis, cancer of the pancreas and esophagus, retroperitoneal sarcoma, etc. In those patients in whom more than one lesion existed as a possible reflex cause of indigestion, Vanderhoof tabulated, according to his discretion, the one most likely to be responsible.

Vanderhoof has the operative notes of 145 of the 246 cases of appendicitis, and of 60 of the 117 cases of cholecystitis. Of a total of 363 cases of appendicitis and cholecystitis, 205 were operated on; replies were received from 134. From these letters it is learned that 61 per cent. are well, 28 per cent. are much improved, and 11 per cent. are not improved. Only one patient in the series died as the result of the operation. This was a case of gallstones in a morphin habitué who also had chronic nephritis, and death occurred forty-eight hours after operation, due to suppression of the urine.

67. **Presence of Antisheep Hemolysin in Guinea-Pig's Blood.**—Cole found that the blood of the guinea-pig occasionally contains a normal antisheep amboceptor which can be detected by control tubes A and B containing saline, 5 per cent. sheep's red blood cells and 10 per cent. guinea-pig's serum, to be tested, in suitable amounts. If after incubation for thirty minutes at 37.5 C., these tubes show any hemolysis then a certain amount of this immune body is present and unless removed will cause practically all of the serum to be tested to be returned negative to the Wassermann test. As complement is thermolabile and inactive at low temperatures, while amboceptor is thermostabile and active at 0 C. it is possible to get rid of the antisheep hemolysin, present in the guinea-pig serum, by mixing it with washed sheep's red blood cells and allowing them to stand one hour at 0 C. After centrifuging the complement is then ready to be used for the reaction. As a means of lessening the action of this troublesome antibody, Cole advises the use of pooled serum for several pigs.

76. **Decomposition of Proteins of Thyroid.**—The details of the method devised by Kendall for alkaline hydrolysis of proteins of the thyroid are as follows: The preparation of finely powdered desiccated thyroid, as fat-free as possible, is added to 90 per cent. ethyl alcohol containing 1 per cent. of sodium hydroxid, in the proportions of 2.5 gm. of thyroid per 100 c.c. of alcohol. The powder is insoluble and settles to the bottom of the container. The alcohol is boiled for forty-eight hours under a reflux condenser. During the heating, ammonia is given off which amounts to about 8 per cent. of the total nitrogen. At the end of this time the alchol has dissolved the greater part of the powder and has a dark brown color. The hot alcoholic solution is now filtered with suction. There is a sticky, tarry residue in the bottom of the flask which contains about 9 per cent. of the total nitrogen, 80 per cent. of the total phosphorus, and 7 per cent. of the total iodin.

The alcohol solution is diluted with water until there is about 75 per cent. of alcohol present, and the sodium hydroxid is neutralized with carbon dioxid or sulphuric acid. If sulphuric acid is used, the alcohol is cooled until the sodium sulphate crystallizes out. This is filtered off and the alcohol is then distilled, leaving a water solution of the split products. If carbon dioxid is used the alcohol is distilled immediately, as the sodium carbonate will not separate satisfactorily. The last traces of alcohol are removed by heating in an evaporating dish on the water bath. The water solution on cooling will solidify to a gelatinous mass if there is much fatty acid present.

The solution is diluted to about 100 c.c. for each 20 to 25 gm. of original thyroid used, and is acidified with 20 per cent. sulphuric acid. This produces a precipitate. The acidification is continued until the addition of more acid ceases to cause a precipitate. The solution is allowed to stand in the cold for several hours, generally over night. The precipitate is filtered without suction and is washed with a little water. This now is the first preparation of *A*. It is allowed to dry on absorbent paper and then is completely desiccated *in vacuo* over sulphuric acid. The filtrate is *B*. It is neutralized with sodium carbonate evaporated to small volume, alcohol is added, and the sodium sulphate crystallized out. The alcohol is distilled off and the resulting solution either desiccated or sterilized for therapeutic use. Fifteen or 20 per cent. alcohol may be used as a preservative.

The dry *A* is extracted with petroleum ether, dissolved in dilute sodium hydroxid, and reprecipitated with sulphuric acid. By warming the solution, after addition of the acid, to about 60 degrees and then cooling to about 10 degrees, the precipitate changes to a sandy, finely divided form easily filtered. *A* in this form is fat-free, and amounts to about 5 per cent. of the total weight of thyroid taken. Its percentage of iodin is about ten times as much as that of the starting material, and for normal glands is equal to about 50 per cent. of the total iodin. The distribution of nitrogen is as follows: *B* conatnis 74 per cent. of the total nitrogen. *A* contains 9 per cent. of the total nitrogen. Alcohol residue contains 9 per cent. of the total nitrogen. Liberated ammonia contains 8 per cent. of the total nitrogen.

83. **Colorimetric Estimation of Uric Acid in Urine.**—The modified technic which Benedict and Hitchcock recommend for the determination of uric acid in urine is as follows: Such a volume of urine as will contain from 0.7 to 1.3 mg. of uric acid (2 to 4 c.c. is usually the right amount) is measured into a centrifuge tube, diluted to about 5 c.c. with water, and treated with 15 to 20 drops of an ammoniacal silver magnesium solution. The contents of the tube are now mixed with a small stirring rod and the tube is centrifuged for one or two minutes. The supernatant solution is then poured off as completely as possible, the tube being inverted, and the inside of the lip touched with a towel or piece of filter paper. The residue in the tube is then treated with two drops of 5 per cent. potassium cyanid solution and the mixture thoroughly stirred with a narrow stirring rod for half a minute. A few drops (0.5 to 0.1 c.c.) of water are added and the solution is again stirred. Two c.c. of the uric acid reagent are then added and the mixture stirred, after which 10 c.c. of 20 per cent. sodium carbonate solution are added, the mixture is washed quantitatively into a 50 c.c. flask at the end of about one-half minute, and diluted to the mark. This solution is compared in a colorimeter with a simultaneously prepared colored solution obtained by treating 5 c.c. of the standard uric acid solution (described earlier in this paper) contained in a 50 c.c. flask with two drops of the potassium cyanid solution, 2 c.c. of the uric acid reagent, 10 c.c. of 20 per cent. sodium carbonate solution, and diluting to the mark at the end of about one-half minute. The standard solution is best set at a height of 15 m.m. in the colorimeter.

This procedure yields quantitative results for pure uric acid solutions and for uric acid added to urine. The figures obtained for uric acid in various samples for urine agree within a small percentage with those obtained by the Folin-Shaffer method. The authors are inclined to regard the new procedure as perhaps more accurate than the titration method of Folin and Shaffer.

84. **Colorimeteric Determination of Uric Acid in Blood.**—The proposed modified procedure for the estimation of uric acid in the blood by Benedict is as follows: Twenty c.c. of blood are added to 100 c.c. of boiling 0.01 *N* acetic acid in a casserole and the mixture is heated to boiling for a moment. The casserole is then removed from the flame and 200 c.c. of boiling distilled water are added. The mixture is then poured on a folded filter, and the residue washed with 50 c.c. of boiling water (heated in the same casserole in which the original coagulation took place). The total filtrate is now transferred to a casserole and boiled rapidly down to a volume of about 25 c.c. This solution is poured into a small flask roughly marked to indicate a volume of 50 c.c. The contents of the casserole are washed quantitatively into the flask with the help of two or three portions of water, heating the water to vigorous boiling, and rubbing the sides of the casserole with a rubber-tipped stirring rod each time. The total volume in the flask should not exceed 50 c.c. after addition of the washings. The turbid solution in the flask is now thoroughly cooled under running water and 2 c.c. of colloidal iron solution are added while the flask is gently rotated. The mixture is then filtered through a small folded filter into a 100 c.c. Jena Florence flask, the residue on the filter being twice washed with distilled water. The filtrate obtained here should be as clear and colorless as distilled water. The solution is now boiled down to a volume of 1 to 2 c.c. (care being taken during the early stage of the process to avoid bumping), then carefully poured into a small centrifuge tube, and the flask washed out with three portions of water (1 to 2 c.c. each), heating each to boiling in the flask and shaking thoroughly prior to transferring it to the centrifuge tube.

The contents of the tube (which should have a volume of from 5 to 10 c.c.) are now cooled and treated with twenty drops of the ammoniacal silver magnesium solution described in the preceding paper. The contents of the tube are mixed thoroughly with the help of a narrow stirring rod, and the tube is then centrifuged for one or two minutes. The supernatant fluid is then poured off as completely as possible, and to the residue in the tube are added one or two drops of 5 per cent. potassium cyanid solution, and the mixture is thoroughly stirred for a moment. A few drops of water are then added and the mixture is again stirred. One or 2 c.c.

of the uric acid reagent of Folin and Denis are then added (1 c.c. if the bulk of the original precipitate was very small, otherwise 2 c.c.), and, correspondingly, 5 or 10 c.c. of 20 per cent. sodium carbonate solution are then added, and the colored solution is washed quantitatively into a 25 or 50 c.c. flask and diluted to the mark with water. This solution is then compared in a colorimeter with the colored solution obtained by treating either 0.5 of 1 mg. of uric acid with 2 c.c. of the uric acid reagent, or 10 c.c. of 20 per cent. sodium carbonate solution and diluting to 50 c.c. at the end of about one-half minute. In conclusion it may be stated that this method appears to give the "free" uric acid in blood. The results obtained for the most part closely parallel those obtained by the Folin-Denis method.

89. **Iodin in Human Fetal Thyroid.**—It is claimed by Fenger that both enlarged and normal sized human fetal thyroids contain iodin at least during the last three months of intrauterine life. Normal sized fetal glands contain relatively more iodin and less phosphorus than enlarged fetal glands.

91. **Human Milk.**—As a result of his studies of human milk the following arrangement is offered by Bosworth as representing the probable condition in which the constituents are present in human milk of average composition. Fat, 3.30 per cent.; milk sugar, 6.50 per cent.; proteins combined with calcium, 1.50 per cent.; calcium chlorid, 0.059 per cent.; monopotassium phosphate (KH_2PO_4), 0.069 per cent.; sodium citrate ($Na_3C_6H_5O_7$), 0.055 per cent.; potassium citrate ($K_3C_6H_5O_7$), 0.103 per cent. and monomagnesium phosphate ($MgH_4P_2O_8$), 0.027 per cent.

95. **Clinical and Roentgenologic Findings in Tuberculosis.**—A careful study of 373 cases by Giffin and Sheldon showed that practically every case of pulmonary tuberculosis with tubercle bacilli in the sputum can be diagnosed independently by the roentgenologist. In almost all of those cases in which a Roentgen diagnosis was positive when the sputum was negative, a review of the histories has corroborated the Roentgen findings. In a considerable number of patients a diagnosis seems entirely impossible by clinical methods although the roentgenologist reports positive findings. These include so-called early cases, healed cases and diffuse tuberculosis. It would seem that a careful study of stereoscopic plates of the chest will show evidences of tuberculosis as early as the author can at present be positive of its existence by any other method. A keener sense of perception is developed through the visualization of lesions and roentgenology has been a stimulus to physicians in perfecting their skill in physical diagnosis. The information obtained from the negative report of a skilful roentgenologist may be of very great assistance in general medical and surgical diagnosis. Finally, the authors emphasize that trustworthy conclusions can be drawn only by one who has had a considerable experience in the reading of stereoscopic plates. The roentgenologist, not the roentgenogram, makes the diagnosis.

97. **Some of Rarer Forms of Joint Disease.**—Moore discusses caries sicca, hydrops articuli, Charcot's disease, or spinal arthropathy and hemophiliac joint.

108. **Septic Factor in Three Plagues.**—That the important rôle of associated septic organisms in the three most widespread plagues of mankind—syphilis, tuberculosis and cancer—is not generally appreciated, is the keynote of Mayo's paper. He says that much of our conception of the primary lesions of syphilis is based on appearances due not to the spirochete alone but to associated septic organisms. Because of the lack of hardness in the base, a hardness due to sepsis, not to syphilis, the diagnosis of chancre of nonvenereal origin is apt to be missed in these days of cleanliness and antisepsis. The diagnosis should rest on microscopic evidence, the finding of the spirochete in the chancre and later by serologic evidence rather than on the gross appearance of the secondaries, the accentuation of which is due to sepsis and therefore in clean people may not be a prominent feature. The importance of a correct early diagnosis in the prevention of systemic infection cannot be overestimated. If this great opportunity is missed, early diagnosis will at least enable careful curative treatment.

Most patients afflicted with tuberculosis do not die from the disease but from the associated sepsis. The surgeon must use great care in operations on pure tuberculous lesions to prevent secondary infections with other organisms and not drain on account of the danger of subsequent infection, unless mixed infection is present. Much of the cachexia of cancer is due to associated sepsis and much of the pain comes from septic infection. Cleanliness and antisepsis give great relief. The high mortality following radical operations for cancer of the large bowel and rectum is mainly due to sepsis and may be reduced one-half by two-stage operations. As much may be said in advanced cancer of the cervix when the preliminary cauterization with the actual cautery, especially the Percy method, followed by a complete hysterectomy, give greater promise of cure with a smaller mortality. Cancers of the surface of the body covered with a sloughing material and surrounded by an extensive inflammatory zone should be destroyed with the actual cautery, and when the induration has disappeared the entire area may be removed with plastic repair of the defect.

111. **Intestinal Toxemia.**—In the treatment of this condition Eggleston states that their efforts must be directed chiefly toward limiting the putrefactive processes of the intestinal tract. This can be accomplished in five different ways: 1. The selection and ingestion of food that is freed from contamination with putrefactive bacteria. 2. The proper preparation of the food for prompt digestion. 3. The selection of a menu that will not furnish an excess of protein material. 4. By preventing abnormal stasis of the intestinal contents.

5. By controlling the intestinal flora so that the putrefactive bacteria are reduced.

119. **Pellagra Treated Successfully with Trisodium Citrate.**—Fossier's patient was given 2 decigrams of cacodylate of soda for twenty-five consecutive days, also daily injections of 1 c.c. of a 10 per cent. solution of trisodium citrate by hypodermic injections. Fever ranged from normal to 102 degrees during the first twenty days of treatment, after which it gradually subsided. The bowels became regular and the skin gradually improved. The mental condition cleared up. At the end of the month the patient was wonderfully improved both physically and mentally and was walking about. When he was discharged at the end of another month all visible evidences of pellagra, the skin lesions, the mental conditions and the gastro-intestinal disorders had disappeared.

137. **Diabetic Coma Not Due to "Acetone Bodies."**—The three cases of diabetic coma studied by Rosenbloom, which differed so completely from the modern idea of acidosis as the cause of coma, were all of the severe type, with no tolerance for carbohydrate, and with a restricted protein intake there was no lessening of the glucose output. They were studied for a period which varied from one week to two months. During this time the urine contained a normal amount of ammonia-nitrogen and showed no trace of acetone, diacetic acid or beta-oxybutyric acid. There was no evidence of any kidney pathology. The urine contained excessive amounts of colloidal nitrogen, neutral sulphur and amino-acids. Death occurred in typical diabetic coma.

In the last case studied 200 c.c. of blood were taken shortly before death. Only faint traces of acetone, diacetic acid and beta-oxybutyric acid were found. The nonprotein nitrogen of the blood serum was normal in amount. This case is especially interesting on account of the fact that about fifty hours before death, showers of granular casts were present in the urine. The urine was cloudy, due to the presence of such an enormous number of casts. The frequent inadequacy of the alkaline therapy, Rosenbloom believes, can be explained on the basis of the fact that the acetone bodies are not always the important factors in the causation of the symptoms in cases of diabetic coma, but that considerable attention must be paid to the study of the excretion of amino-acids, polypeptids, and certain unknown substances in this disease.

5. **Treatment of Fractures of Femur Due to Projectiles.**—The method used by Tubby is a combination of plaster of Paris and strips of soft iron. The plaster of Paris bandages are rolled on either over flannel bandages or a stockinet garment, and strips of malleable iron. The apparatus is applied under pulley extension and full anesthesia.

7. **Gastric Analysis.**—Heaton maintains that gastric analysis by the ordinary method is not the analysis of the gastric juice, but is rather the analysis of a mixture of this with the remains of the test meal. He points out that if it were known how much of the mixture was meal and how much was gastric juice, both difficulties would disappear, for it would become possible to calculate the actual composition of the gastric secretion. These results he has attained by adding to the test meal some substance at a known concentration, and then estimating the concentration of the substance subsequently in the fluid obtained for analysis. For

this work the substance used has been urea. To an ordinary test breakfast, consisting of toast and a pint of tea, 5.72 gm. of urea are added, making a 1 per cent. solution. The concentration of the urea in the fluid subsequently obtained indicates the degree of dilution by gastric juice which the fluid of the meal has undergone. The conditions in which this refinement of gastric analysis is of value are: In cases in which there is abnormally rapid or abnormally slow emptying of the stomach through the pylorus; and in cases in which an increased or decreased secretion simulates or is indistinguishable from an increased or decreased acidity.

16 Recent Research Relating to Undulant or Mediterranean Fever. P. W. Bassett-Smith.

12. **Method of Treating Wounds.**—Of the substances which the authors tested, boric and salicylic acids, cresol and phenol seem to be the most useful. Cresol and phenol have very considerable activity at a distance both as inhibitory and as destructive agents, and when combined in a wax and lanolin base, go on diffusing for a considerable time. The result is that they prevent the growth of bacteria over a considerable area, and are able also to destroy the ordinary pyogenic nonspore-bearing bacteria over the greater part of that area. The mixture of boric and salicylic acids is more potent in both directions, and, apparently, as evidenced by experiments on guinea-pigs, can prevent the action of spore-bearing organisms also. In some ways, however, this mixture of boric and salicylic acids is not so suitable as the others, especially in that it is not stored up in the same way, but the combination with cresol or phenol pastes seems very efficacious in animals.

Boric and salicylic acids have not acted so well in the form of pastes as in powder. In a paste with lanolin and wax it does not diffuse at all well, and in the experiments on animals the paste with gum tragacanth, which diffuses very well in agar, did not act so well as the powder. The authors, therefore, propose that salicylic and boric acids in equal parts should be used as a powder and thickly dusted over the wounds so far as possible, and that its action should be reinforced by the injection of cresol paste (20 per cent. in lanolin and wax base) into the interior of the wound in various directions.

17 *Vibrio (Vibrio Kegallensis Cast., 1913) Isolated from Cases of Paracholera. A. Castellani.
18 Spinal Analgesia in Native Practice. A. Y. Massey.
19 An Attempt to Colonize "Millions" in Malay Peninsula, for Antimalarial Purposes. C. Strickland.

17. **Vibrio Isolated from Cases of Paracholera.**—From two cases of clinically cholera-like disease, and from the water of a well near which several cases had occurred, a vibrio was isolated by Castellani which is biologically different from the true *V. cholera.* In a preliminary note, published some time ago, referring to the first case alone, he named it *V. kegallensis cast.*, 1913. Though its pathogenicity has not been completely proved the probabilities are, in his opinion, that it is the cause of certain cases of cholera-like disease, or "paracholera."

23. **Treatment of Gunshot and Shell Wounds.**—Adopting Wright's recommendations, Whitehouse treated a series of shell and gunshot wounds of varying degrees of severity by the application of hypertonic saline solution. The results obtained were sufficiently convincing to prove the correctness of Wright's views. At the same time, the degree of lymph lavage produced by a saline solution was not great, and although sepsis diminished and wounds healed the important factor of time was not sensibly diminished. It appeared to Whitehouse, therefore, that even better results were possible by employing a solution of greater osmotic power. He therefore had a solution of liquid glucose containing sufficient phenol to have a strength of 1:80. This solution was applied directly to the wound surfaces and by means of plugs was carried into the recesses of the same. The results quite exceeded his most sanguine expectations. In a few hours sufficient lymph was exuded in each case to saturate the whole of the wool and bandage covering the part. Coincidently the purulent character of the discharge changed, and in a day or two a healthy granulating surface remained. The cases treated by phenolized glucose dressings include severe compound fractures and large lacerated wounds of the extremities, some involving the elbow joint and necessitating excision of the joint. One case of shell wound of the cranium exposing the dura mater and injuring the superior longitudinal sinus was also so treated. All the cases made a rapid recovery and were ready for transfer at the end of seven days.

The routine which Whitehouse now adopts in the treatment of all septic wounds may broadly be expressed as follows: (1) Removal of foreign bodies after location by Roentgen rays and if anatomically possible; (2) application of efficient drainage by enlargement of the wounds of entry and exit, or by fresh incisions into the tissues if required; (3) removal of as much necrotic and contused tissue and blood clot as possible; (4) application of warm hydrogen peroxid (20 volts) to the recesses of the wound if anaerobic infection is suspected; and (5) establishment of profuse lymph lavage by the application of a solution of phenolized glucose on white gauze dressing or gauze plugs.

30 *Two Cases of Patency of Ductus Arteriosus. T. W. Griffith.
31 Alterations in Arterial Structure and Their Relation to Syphilis. H. M. Turnbull.
32 Mumps. A. Feiling.

30. **Patency of Ductus Arteriosus.**—The two examples of patency of the ductus arteriosus reported by Griffith to have occurred in patients in whom the affection was recognized during life. One of these succumbed to infective endocarditis and the diagnosis was verified on the postmortem table. In the other the condition was associated with some further anomaly of the great vessels and with a development error which had given rise to cyanosis, for this is a symptom which is not often met with in uncomplicated cases of patency of the arterial duct.

In the fatal case there was found considerable enlargement of the heart, which weighed about 14½ ounces. There was marked hypertrophy without notable dilatation of the right ventricle. There was recent pericarditis, and before the heart was removed there was found on the anterior and left aspect of the pulmonary artery, which was generally dilated, a large bilobed aneurysmal swelling. There was old standing disease of the mitral valve with moderate stenosis of the orifice and both this valve and the aortic segments presented large fungating masses of vegetations. Evidence of recent endocarditis was found at the junction of the two posterior segments of the pulmonary valve. The lumen of the pulmonary artery was almost occluded by a large mass of blood-stained vegetations, which was gently adherent to the walls of the vessel at two situations. One of these was at the anterior and left aspect of the artery, in which there was a double concavity corresponding to the convexity seen from the outside; the other was around the opening of the ductus arteriosus, and into this there projected a conical mass of vegetations so as completely to occlude the aperture. When the ductus was cleared of this it permitted the passage of a No. 9 catheter. The space left for the passage of the blood between the mass of vegetations and the wall of the vessel was probably much greater during life than one might expect from an inspection in the postmortem room, in which the dilating influence of the blood pressure would be absent.

37 *Wounds of the Eyes in War. (Blessures oculaires de guerre.) A. Darier.

34. **Meningococcus Arthritis.**—Netter and Durand have found a suppurative joint trouble a comparatively frequent complication of cerebrospinal meningitis, second in frequency only to otitis media, but it has always terminated favorably. The joint regained its normal functioning in every case but recovery seemed to be hastened by injection of antimeningococcus serum directly into the joint. In the last seven years this suppurative arthritis was encountered in 11 of their 200 cases of cerebrospinal meningitis. Various joints were affected and sometimes several at one time. In 5 cases no microbes could be cultivated from the joint or revealed by the microscope. In this group the arthritis developed later than in the others. In one infant of 10 months meningococci were found in the feet processes while the meningitis was at its height. As this subsided under intraspinal serotherapy, the toe processes subsided also, but then pus accumulated in one ankle. No meningococci could be cultivated from it however, and the suppurative process promptly disappeared at a single injection of antimeningococcus serum. In one child 1 year old there were eleven separate suppurative processes. In four infants the suppurative processes were in fingers and toes; in 2 of these purpura was the first sign of anything wrong. The ages of the patients ranged from 10 months to 30 years. The meningitis terminated fatally in 4 cases. In addition to the above 11 cases they report the death of a 3 months' babe from a primary meningococcus arthritis in the shoulder; the meninges were apparently normal.

This meningococcus arthritis resembles very much the primary or secondary arthritis set up by pneumococci. They both are more benign than joint trouble of other origin, but the meningococcus affection has the advantage of a specific medication, namely, direct local injection of antimeningococcus serum.

37. **Wounds of the Eyes in War.**—Darier comments on the great increase in the number of cases in which the eyes have been wounded since the close fighting in trenches. The head being most exposed is more often hit than the rest of the body and he has already encountered a hundred cases of injury of the eyes, many of them requiring extensive plastic operations on the lids or to provide a support for an artificial eye. He urges a special colored tag for a soldier whose eye has been injured so that he can be rushed with the minimum of delay to an eye specialist. First aid should be with a soft bandage, an injection of morphin if the pain is severe and, if there is much destruction of tissue, two or three doses of antitetanus serum.

40 *Impressions in the German Military Hospitals. (Eindrücke aus deutschen Kriegslazaretten.) T. Kocher.

40. **Impressions in German Field Hospitals.**—Kocher remarks that "against the dark background of the war, there stands out in bright relief the care of the wounded, wonders of aid and Christian sympathy on a scale beyond anything ever experienced or anticipated." In these thirty pages Kocher sketches the whole organization and working of the care of the wounded and sick in Germany as he has made his rounds of investigation, and he urges the authorities in his own country, Switzerland, to make it possible for young physicians and surgeons to study in the arena of war. The unprecedented opportunity now afforded is a university course in up-to-date war surgery. The principles of surgery, he adds, are the same under all circumstances, but the primary healing of wounds in peace scarcely prepares a surgeon for work in war. He comments in particular on the way in which the chief of the German army medical service has always kept in close touch with the leading surgeons and clinicians throughout the country, attending all their national annual meetings and keeping posted as to their work and achievements. He called them in at once as consultants in this war, and their advice, as *Generalärzte*, has had the greatest influence on the whole organization of the medical service. The wounded and sick, friends and foes alike, wherever Kocher went (Freiburg, Strassburg and Frankfurt) he remarks in conclusion, have such confidence that everything possible is being done for them that this is proving an important factor in the cure.

47 *When a Country is at War, Can a Minor Operation, To Remove Physical Disability for Military Service, Be Imposed on a Man without His Consent? (Das Recht und die Pflicht zu operativen Eingriffen an Heerespflichtigen in Kriegszeiten.) F. R. Brewitt and Ebermayer.

42. **Roentgenotherapy of Chronic Eczema.**—Meyer has been much impressed with the complete cure of chronic or subacute eczema of long standing in thirty-eight cases treated with hard Roentgen rays filtered through 1 mm. aluminum. The rays are of the 10 or 11 Wehnelt standard of hardness and the filter is applied close to the tube, thus avoiding the secondary rays generated when the filter is close to the focus. The distance of the field from the tube was always 20 cm. Some of the patients had more than one patch of eczema. None proved refractory and the cure was sometimes realized with a few exposures, others requiring a course of weekly exposures until a total dosage of 2.5 full doses had been given.

In three cases the eczema was of ten years' standing, in the others from seven weeks to five years. The chief advantages of roentgenotherapy for this purpose are the short time required; four weeks are ample, the regularity of the effects attained and the fact that this treatment scarcely interferes at all with the patient's occupation. He warns that a syphilitic skin affection is liable to be mistaken for eczema. This occurred in two cases brought to him for Roentgen treatment after failure of other measures. He applied the Wassermann test which elicited a vigorous reaction. and the "eczema" healed up completely in a week under two injections of a mercurial salt after having resisted all other measures for five years. In a second case the supposed "eczema" of the palm yielded to the Roentgen exposures after proving refractory to salves and other measures for four years. There was a violent reaction, however, to the final dose. The "eczema" recurred after a brief interval, and this time became aggravated under roentgenotherapy. The Wassermann test then applied gave positive findings and specific treatment was at once instituted. He is convinced that the hard rays are biologically more active than the soft rays. In conclusion he warns against any attempt at roentgenotherapy during the acute phase of eczema.

44. **Stereoscopic Roentgenography.**—Brauneck deplores that so few practitioners have mastered the comparatively simple technic for stereoscope roentgenography. It is especially instructive in localization of metal foreign bodies and for all kinds of topographic investigation, especially with fracture of the pelvis and of the bones in the hand and foot. The stereoscopic Roentgen picture is alive, he remarks, in comparison to the dead, flat picture.

45. **Osteomyelitis of the Spine after a Wound in War.**—Wolff quotes Henle's compilation of five cases of acute osteomyelitis with a traumatic origin, and Grisel's compilation in 1903 of fifty-six cases of acute infectious spondylitis. He then describes a rapidly fatal case in a soldier, the first symptoms of the osteomyelitis not developing until six weeks after a scrap from a shell had been driven into his neck. The bleeding was arrested at once by ligation of the artery injured, the surgeon being close at hand, and three weeks later the scrap of metal was extracted through the esophagus. Three weeks after this signs of spinal meningitis developed and the man died within a month. Necropsy showed that the third cervical vertebra had been injured by the scrap of shell and osteomyelitis had developed with local meningitis. The case teaches that foreign bodies should never be removed through the esophagus wall, opening up a portal for infection. It also emphasizes the necessity for treating every case in which there is a suspicion that a vertebra has been injured with extension or a plaster cast. If the scrap of shell had been removed in this case from an opening in the rear, provision for drainage, etc., would have been realized and the infectious process might have been warded off.

47. **Right to Perform Operations to Remove Physical Disability.**—Brewitt relates a number of instances of wounded soldiers who are developing into helpless cripples because they refuse to permit the minor operations that would give them a useful limb instead of the present contracted member doomed to atrophy. The men are unable to estimate the fate they are preparing for themselves and he thinks that in such cases, as also for men who have been exempted from military service on account of some physical defect easily remedied by a minor operation, the military authorities should be able to interfere. He refers in particular to hernias, benign tumors, excrescences, etc. If any mishap should occur the family would be entitled to a pension just as if the man had fallen on the field. He calculates that from 30,000 to 40,000 men might thus be added to the ranks who are otherwise eminently fitted for military service. Ebermayer discusses the question from the legal standpoint, regarding it as extremely doubtful whether the authorities have any right to interfere in this way with a man's right to his own person, even during the exigencies of war.

50 *Typhus. (Kriegstyphus.) H. Boral. Concluded in No. 17.
51 Trauma and Infectious Complications. (Trauma und Wundinfektionskrankheiten.) E. Schepelmann.
52 *Treatment of Open Wounds. (Zur Wundbehandlung.) Wilcke.
53 *Diabetes Following Trauma. Rings.

48. **Heart Disturbances with Constitutional Physical Inferiority.**—Schmidt discusses this subject as it bears on military efficiency, reviewing the signs which permit recognition of heart disturbances resulting from physical inferiority. In testing the heart functioning in dubious cases, it is very instructive to have a control person of about the same build, with normally functioning circulatory apparatus, go through the exercises with the one being tested. The pulse before and after the exercises, the count, the quality, the blood pressure, the respiration rate, the apex beat, the complexion, perspiration, etc., are all useful in estimating the functional capacity of the cardiovascular apparatus. The interval before the previous status returns is especially instructive.

50. **Typhus.**—Boral has had 760 cases of typhus in his charge in the eastern seat of war. In 24 cases actual psychoses developed; in 15 they were of the megalomania-paranoia type, in 3 kleptomania. Deafness is an important symptom in typhus, he remarks, as in no other disease does deafness come on so regularly with the high temperature. The slow pulse was in striking contrast to the fever in nearly every case. The mortality was 9 per cent. exclusive of the moribund cases. A number of patients developed pyemic processes during convalescence and they often took the form of cold abscesses. Those in the abdominal walls simulated lipomas; sometimes the abscesses ran a symptomless course. Acute otitis media developed in 31, parotitis in 15, orchitis in 10, pneumonia in 39, and in 36 there was intestinal hemorrhage, and a relapse in 24 cases.

52. **Treatment of Open Wounds.**—Wilcke has found it of great advantage to pour into jagged wounds liquid paraffin in which iodin has been incorporated in the proportion of 1 to 300 parts. When the wounds are cleansed he uses a salve with 1 part each of iodin and potassium iodid to 100 parts of petrolatum.

53. **Diabetes Following Trauma.**—In the case reported severe neurasthenia developed a few months after the man had fractured the sixth, seventh and eighth thoracic vertebrae. The neurasthenia was accompanied by symptoms of diabetes. They continued a progressive course and when the man died, thirteen years after his fall, the courts accepted the traumatic origin of the diabetes and awarded an indemnity to the heirs.

April 22, No. 32, pp. 497-512

61 *Alcohol in Surgery. A. Pellegrini.

59. **Gastric Psychoneuroses.**—Calligaris thinks that clinicians are too apt to regard the majority of stomach affections too exclusively as symptomatic, while the neurologists regard

them exclusively as purely functional and of psychic origin. The treatment of these two extremes is exactly opposite, and woe betide the nervous dyspeptic who falls into the hands of a clinician who disregards the nervous element or, vice versa, the patient with organic trouble whose precious time is wasted on psychotherapy alone. Calligaris classifies gastric neuroses in two types: the false, symptomatic or secondary, and the true, the essential or primary neurosis of the stomach. The history of this latter type is scarcely fifty years old. The symptomatology is rich indeed. The kaleidoscopic picture is the chief point in differentiation. Generally there are both sensory and motor symptoms. Vomiting may occur in this type but the possibility of hematemesis of purely nervous origin is generally denied. Calligaris is convinced that this denial should not be too absolute, but he does not believe in the possibility of an exclusively gastric neurasthenia.

The examination of the stomach should be done with extreme caution and tact to refrain from suggestion that may add new features to the clinical picture. Organic trouble should be suggested more readily if the patient is near or past 50. A purely functional stomach trouble may lead to an organic affection, thus setting up a grave vicious circle. There is no doubt that certain patients with true gastric neuroses have recovered under courses of dieting and medicines, but there is also no question of doubt that hosts of others have had their gastric neurosis bred into a chronic and possibly an incurable phase by such measures.

He has had opportunity to study fifty individuals with true gastric neuroses. It was easy to trace the relation between cause and effect, between emotions, phobias, autosuggestion and suggestion from others, and the development of the neurosis, to follow day by day and hour by hour the course of the symptoms from the stomach as they paralleled the fluctuations in the moods and emotions, and to note the regular transient aggravation of the neurosis after certain happenings and the rapid and progressive improvement under psychotherapy. Disturbances in secretion, motor functioning and sensation, in patients growing more and more debilitated, disappeared surprisingly fast under appropriate psychotherapy, and the downward trend toward mental anorexia was thus arrested. Some of these patients had long complained of loss of appetite with inability to eat, and had lost from 20 to 33 pounds, but under eight or ten weeks of isolation and psychotherapy, they regained strength and almost their former weight. The outcome confirmed the correctness of the diagnosis and treatment; if treatment had been on the basis of an assumed organic trouble, the old disturbances would have been kept alight or fanned into a flame. It is in these cases that "local treatment kills; general treatment saves." Both Dubois and Dejerine believe that fully four-fifths of dyspeptic disturbances are of purely nervous origin. Even reducing this figure by one-half, leaves a large number of which this is certainly true. They owe their origin to some emotional stress or to suggestion from within or without, and mostly to suggestion from some medical treatment which fixes the gastric neurosis still more firmly in the patient's mind, by the questions asked, repeated examination, restrictions in the diet, and polypharmacy. "There are stomachs for the chemists and the radiologists and also for the psychologists, the psychiatrists and the neurologists," he adds, "Nature presents her phenomena with a thousand aspects but man is liable to see only the one aspect which his eyes have been specially trained to see."

60. **Helminths in the Bile Ducts.**—Dalla Valle gives an illustration of five adult ascarides found plugging three of the bile ducts at necropsy of a man of 26 who had gradually become insane after the age of 18. Others were found in the intestines. The only complication noted had been the stasis of bile. There was no tendency to cholelithiasis.

61. **Alcohol for Surgical Use.**—Pellegrini extols the advantages of alcohol for sterilization of the hands, etc., especially the denatured alcohol now supplied the hospitals in Italy. The denaturing is done with benzol and picric acid, and the product thus obtained has several points of superiority over alcohol denatured by other methods.

71 Forking Ureter with Movable Kidney. G. Becchérle.
72 *Injection of Alcohol into the Spinal Ganglia. A. Chiasserini. Commenced in No. 1.

67. **Contraindications for Salvarsan.**—Pontano affirms on the basis of considerable personal experience and study of the literature, that, if the heart and kidneys are sound, salvarsan is very slightly toxic. This may be accepted also even if the heart and kidneys are not quite sound, but anything pathologic is perfectly compensated. Symptoms of toxic action have been noted in about 15 or 20 per cent. of the cases in which it has been systematically given. The symptoms are slight and transient and testify to a peculiar individual intolerance, not to any special nature of the disease or its localization. Syphilitics with internal disease, whatever its nature, can be given salvarsan without fear provided the heart and kidneys are sound. Insufficiency on the part of either of these organs is an absolute contraindication, and insufficiency of the liver, a relative contraindication.

69. **Influence of Animal Charcoal on Peptic Digestion.**—Divella experimented with bone charcoal mixed with the mucosa taken fresh from the stomach of a pig or dog, and ground in a mortar. He found that the digestion was materially accelerated by the charcoal admixture in a proportion of 22.05 per cent. Larger or smaller proportions were far less effectual. In the presence of a poisonous substance, strychnin, arsenic, etc., digestion proceeded much more effectually with the charcoal than without. He ascribes its favorable influence to adsorption of the poisons and of ferments, etc., that tend to inhibit digestion. The conclusion seems evident, he adds, that animal charcoal will prove beneficial in all cases of gastric dyspepsia, abnormal fermentations or bad breath, in short, whenever digestion in the stomach is deranged from any cause.

70. **Tuberculosis of the Tongue.**—Stropeni comments on the remarkable rarity of tuberculous lesions in the tongue. It seems to indicate unusual resisting power on the part of the tongue tissues. Hence the prognosis is bad when a secondary process develops in the tongue as this is a sign that the general resisting power is at a low ebb. In twenty-nine cases on record the tuberculous lesion in the tongue was mistakenly assumed to be cancer, and extensive mutilating operations were done. Rapid and fatal recurrence followed in most of the cases, and signs of tuberculosis in other organs showed that the tongue affection had been a secondary process, the

system already undermined. A primary tuberculous process in the tongue is a different matter, and a complete cure is the rule after thorough excision of the focus. Curetting and cauterization are inadequate; in advanced cases, roentgenotherapy may be preferable to excision. The focus should always be removed also with a secondary lesion unless the lungs are involved. When this is the case, roentgenotherapy is better. Stropeni gives references to recent literature on tuberculosis of the tongue, including fourteen Italian and fourteen German works and only three from English literature.

His attention was called to the subject by a case of apparently primary tuberculosis of the tongue in a robust man of 33. A hard, whitish bunch developed on the frenulum, where it joins the base of the tongue. It soon ulcerated and was very painful. After two months of household remedies, he entered the hospital where mercurial treatment was instituted, notwithstanding the negative Wassermann, and the lesion was repeatedly cauterized. Under three months of this the ulceration grew worse and worse, the neighboring glands became involved and suppurated, with fistulas. Then the tuberculin skin tests and inoculation of guinea-pigs with pus gave positive reactions but no tubercle bacilli could be detected in the sputum. Treatment was then changed to merely rinsing out the mouth with mild boric acid solution, and the angry lesions retrogressed to some extent, one fistula healing. The ulcerations on the tongue were then exposed to the Roentgen rays and benefit was apparent almost at once. Eight sittings were given in the course of a month, under which the tongue affection healed smoothly and completely. The patch of swollen glands in the neck was then excised as the suppuration kept up. The cure was then complete and there have been no signs of recurrence during the six months since and the man feels entirely well.

72. **Injection of Alcohol into the Spinal Ganglia.**—Chiasserini concludes his monograph with references to 159 articles, including several in The Journal. He has studied the technic on dogs and on cadavers, and declares that it is possible and practicable to interrupt, by injection of alcohol into the spinal ganglion, the reflex arc responsible for a number of morbid syndromes and, in particular, for the gastric and intestinal crises in tabes. The technic is simple and easy, he declares, and it promises to be entirely harmless. Even if the alcohol does not get inside the ganglion, and the injection is thus merely periganglionic, it probably will block the nerve to a certain extent. He gives illustrations of the surgical anatomy and the technic he found best adapted for the purpose.

73. **Cytotoxic Serums in Treatment of Exophthalmic Goiter, etc.**—This experimental research was done at the Genoa university clinic in charge of Maragliano. It was based on the fact that in animals treated systematically with the extract of an organ their serum acquires in time a destructive action on the cells of the organ in question. Cytotoxic serums were thus obtained for the thyroid and suprarenals. It seems a plausible assumption that a serum endowed with a destructive action on the thyroid would aid in reducing symptoms caused by excessive functioning on the part of the thyroid. Test tube experiments in this line gave encouraging results: mixing with 1 c.c. of the patient's serum the amount of cytotoxic serum known to neutralize the minimal lethal dose of thyroid extract, then adding one drop of an alexin and incubating for an hour, then adding the minimal lethal dose of thyroid extract and one more drop of alexin and incubating for another hour. This mixture then injected into a rabbit's vein promptly kills the animal if the patient in question is suffering from hyperthyroidism, while it does not harm the animal if there is hypothyroidism. The mechanism of this is explained and the method suggested as useful for differential diagnosis.

Also in treatment of hyperthyroidism, the cytotoxic serum would have the effect of binding the excess of thyroid principles in the blood. Its action would thus be analogous to that of the serum of thyroidectomized animals, now often used in treatment of exophthalmic goiter. The blood of these thyroidectomized animals contains all the principles which normally are neutralized by the thyroid gland. Cytotoxic rabbit serum in treatment of exophthalmic goiter was given a trial at the clinic in 1911 in one case, but the supply of the prepared serum ran out in two weeks, and the attempt had to be abandoned. All the evidence so far obtained speaks strongly in favor of the possible utilization of cytotoxic serums in exophthalmic goiter. The other ductless glands can scarcely be considered in this respect as they cannot be spared from the body like the thyroid.

75. **Oxygen and Carbon Dioxid in the Blood in Uricacidemia.**—Preti recalls that an aqueous extract of liver tissue has the power to destroy uric acid added to it in the presence of oxygen. The uric acid is reformed if the oxygen is replaced by carbon dioxid. Preti and other Italian workers have reproduced these phenomena with artificial circulation through the liver, first oxygenating the blood, to destroy the uric acid, and then reforming it with the aid of carbon dioxid. Preti's further research has shown that both the phenomena are the work of ferments in the blood. Animals breathing air with much carbon dioxid eliminate larger quantities of uric acid through the kidneys, and the uric-acid content of the blood is higher. Recent investigation of twelve persons with attacks of gout, tophi and high uric-acid content in the blood, showed from 5 to 18 per cent. oxygen in the blood, the majority approximating the lower figure. The carbon dioxid content was never found less than 50 per cent., the range being from 51 to 76 per cent. In the healthy controls, the oxygen range was from 16 to 23 per cent. and the carbon dioxid from 38 to 44 per cent. These findings throw light on the familiar experience that gout affects persons with defective oxidations owing to a sedentary life, muscular inanition, depression of the heart action, etc.

77 *Continuous Extension in Treatment of Sciatica. I. Svindt.

77. **Extension Treatment of Sciatica.**—Svindt has applied extension, as for a fracture of the neck of the femur, in 26 of the 41 cases of sciatica in his service in the last five years. The youngest patient was 22, the oldest 74, and the extension relieved them of their pain and in most cases led to a permanent cure. The extension was kept up for about three weeks, and was followed by massage and hydrotherapeutic measures for another week or ten days, to complete the cure. The average stay in the hospital for the 41 patients was forty-four days, but extension was applied only in the severest cases. In one case since there was recurrence of the sciatica about six weeks afterward, but another course of extension treatment at home cured him and there has been no trouble since. Only one other patient reports recurrence of the sciatica; it has returned several times but always in such mild form that it has not interfered with his occupation. Svindt's experience on the whole has thus been very favorable with this extension method of treating sciatica. The technic is so simple that any practitioner can apply it. The relief from pain and the permanent benefit are probably due to the complete rest of the limb and the musculature. It is not probable that the extension applied is enough to really stretch the nerve. He begins with a weight of 4 kg., gradually increasing it to 7 or 8 kg. The last trace of pain generally subsides when a weight of 7 kg. is reached (15.4 lb.) He gives a sedative the first day or so if absolutely required, and follows with salicylates for a few days, with a fever diet and then a full diet.

THE PHENOLSULPHONEPHTHALEIN TEST IN CHRONIC NEPHRITIS [*]

ARTHUR R. ELLIOTT, M.D.
CHICAGO

Ever since Schlayer and his co-workers elaborated their system of differential renal function testing, much attention has been given to the subject of kidney function tests in nephritis. Clinical requirements demand not only that such a procedure shall be simple and easily available for clinical employment, but that it shall be of demonstrated accuracy; otherwise it may lead to faulty deductions in prognosis and possibly to blunders in diagnosis. However attractive it may appear from the pathologic point of view, to estimate the degree to which the different anatomic elements of the kidney are involved, it would seem that the mixed type of nephritis encountered clinically practically disposes of the attempt to weave fine diagnostic distinctions about the reactions secured by differential function tests. With clinical nephritis of the simplest type, there is enough general structural involvement to make conclusions as to special function involvement hazardous.

Many considerations render the study of renal function in detail an extremely complex problem. To base conclusions on differential tests assumed to reveal glomerular, tubular or vascular impairment necessarily implies that we can test the individual functions of the kidney, and presupposes a much more definite knowledge of the physiology of that organ than we in fact possess. Moreover, it is only in acute fatal cases of nephritis that anything like pure system involvement—glomerular or tubular—exists. As the matter stands, the only methods available for clinical usage are such as furnish information regarding the total function of the kidneys—their general excretory capacity.

THE PHENOLSULPHONEPHTHALEIN TEST

Tests for estimating general renal efficiency have consisted mainly of the introduction of various dye substances, which are excreted more or less completely in the urine. General agreement accords first place among these tests to the phenolsulphonephthalein test of Rowntree and Geraghty,[1] introduced in 1910. It was at first employed most extensively in surgical cases, especially with reference to the question of operations on the urinary organs. It is equally applicable to medical cases, but the results are considerably more difficult of interpretation, and it is only recently that sufficient observations have accumulated to give it a fixed status in this class of cases. The harmlessness and simplicity of the test render it an easily available clinical procedure. In its application to nephritis Rowntree and Geraghty have shown from careful clinical and pathologic studies that the amount of phenolsulphonephthalein excreted varies as a general rule in rough ratio with the extent of the renal damage. In fatal uremia only traces or none at all of the dye appear in the urine for the two-hour interval, while in mild and moderate grades of nephritis the amount recovered from the urine may be normal or nearly so. These authors assert further that in cardiorenal cases when the heart is failing and the kidneys become passively engorged, a low phenolsulphonephthalein output is observed at first, rapidly rising subsequently as the heart action improves and venous engorgement subsides. An increase in the phenolsulphonephthalein index in such a case may be the earliest sign of restoration of compensation and represents a favorable prognosis. *Per contra,* a low excretory capacity, persisting after clinical evidence of cardiac improvement, points to a severe nephritis and a less favorable prognosis.

The authors of the test emphasize the purely empiric character of the investigation, owing to our lack of sound information as to the physiology of urinary secretion, and while attaching a high degree of prognostic value to its findings when positive and clear cut, they warn against too general prognostic interpretation, inasmuch as the test yields information only so far as renal efficiency or inefficiency can be estimated, whereas death may occur in chronic nephritis from many other factors, cardiac and cerebral in particular, concerning which the test gives little if any information. This method in common with other function tests must in consequence be considered always in conjunction with general clinical study; otherwise prognosis is made dependent on laboratory technic, which is always a hazardous alternative.

Coincidently with the investigation of the functional adequacy of the kidneys in nephritis, attention has been directed to the estimation of the incoagulable or nonprotein nitrogen of the blood as offering a valuable means for securing information of prognostic value. Studies of this nature are particularly to be desired in the investigation of nephritis, since urine analysis cannot reveal the stage of accumulation of waste products, an accumulation that may vary from almost normal figures to enormous increase in uremia.

THE INTERPRETATION OF RESULTS

Although the technic for nonprotein nitrogen determination offers no difficulties to the well-equipped chemical laboratory, it is so technical and time-consuming as to be beyond the capabilities of the clinician for routine employment. Studies of renal efficiency by the phenolsulphonephthalein test consequently offer great advantage as to convenience and ease of application. The chief drawback attaching to this method of estimating kidney permeability lies in the interpretation of results, for it is quite conceivable that the rate of elimination of a foreign dye substance may bear no definite relationship to the efficiency of the kidneys in excreting metabolism products.

Cases have been reported (Foster,[2] Baetjer[3]) in which the phenolsulphonephthalein test gave practically normal figures, yet fatal uremia resulted shortly after the tests were made.

Rowntree, Fitz and Geraghty[4] assert that phenolsulphonephthalein is excreted solely by the tubular epithelium, a contention supported by Potter and Bell[5] from their studies of experimental tartrate nephritis and it is conceivable that these reported cases may have been nephritis of predominantly glomerular type.

Such excretory paradoxes emphasize the loopholes for error in any general interpretation, however firmly the rule may appear to be established by results. The same thing is true of nonprotein blood nitrogen estimations in nephritis, a number of instances being reported in the literature, of uremia developing in the face of normal waste nitrogen content. However obscure and against the rule such exceptions may be, they serve to establish a discount against too rigid interpretation of any routine investigation. They serve to accent our ignorance of the exact nature of uremia and leave open the question of whether so profound a disturbance of the entire metabolism as results from severe nephritis there may not be some other factor, in addition to the action of urinary retention bodies, which is as yet unappreciated.

As the nonprotein index in the blood is admittedly the most reliable criterion of renal efficiency, it is desirable to correlate the elimination of phenolsulphonephthalein with the actual retention of nitrogenous waste in the blood. This has been undertaken by Frothingham, Fitz, Folin and Denis[6] in experimental uranium nephritis. The results of their investigation demonstrate that in general the tests parallel each other as indicators of renal function, varying from normal during the course of the nephritis and returning to normal as the nephritis heals, with this important difference, that, whereas the amount of phenolsulphonephthalein excreted shows the renal function at the time of the test, the amount of nonprotein nitrogen of the blood measures the accumulating difference between the production of waste nitrogen bodies in the metabolism and the quantity excreted.

The time element — the duration of the nephritis — becomes, therefore, an important factor in the result. It has long been known that during the course of any nephritis there are certain periods when the urinary constituents are normal in amount as compared with the intake, and other periods when they may be increased or decreased. These functional eccentricities of the kidneys, imperfectly understood, may have a bearing on some of the inconsistencies of excretory tests. Frothingham and Smillie[7] carried out a series of observations on the nonprotein nitrogen and the phenolsulphonephthalein excretion in seventy-seven cases of chronic nephritis. From their charts it appears that the phenolsulphonephthalein excretion steadily falls as the amount of nonprotein nitrogen of the blood increases, phenolsulphonephthalein practically ceasing to appear in the urine when the nonprotein nitrogen reaches 100 mg. (four to five times normal). In a moderate number of cases a surprisingly low phenolsulphonephthalein output was shown for which no cause could be found, either from clinical findings or laboratory tests. They consider it fair to state that a considerable individual variation above and below the expected average may occur with the phenolsulphonephthalein test for which no explanation can be found.

In the main, the relation between nonprotein values and clinical findings is fairly exact. No nonnephritic cases showed accumulation. All their cases with nonprotein nitrogen above 50 mg. per 100 c.c. of blood gave clinical evidence of severe nephritis. In some of these cases the phenolsulphonephthalein excretion was unexpectedly good. On the whole, however, the nonprotein nitrogen varied inversely with the excretion of phenolsulphonephthalein in the urine. The accumulation of waste nitrogen seemed to be much less influenced by cardiac and other complicating factors than was phenolsulphonephthalein excretion.

Agnew[8] undertook studies to determine what relation, if any, existed between phenolsulphonephthalein output and nonprotein nitrogen of the blood. He concludes that, in general, cumulative phenomena occur only when the excretion of phenolsulphonephthalein falls below 40 per cent. in two hours. This is in keeping with the observations of Folin, Denis and Seymour.[9] Tileston and Comfort[10] found that cases of chronic nephritis without symptoms of uremia showed normal or only moderate cumulative signs, the uremic cases, on the contrary, yielding a great increase in the nonprotein blood nitrogen, the excretion of phenolsulphonephthalein being roughly proportionate to the degree of retention.

Rowntree, Fitz and Geraghty[4] show that chronic passive congestion of the kidneys gives rise to reduced secretion of phenolsulphonephthalein in the urine, without marked increase in the incoagulable nitrogen of the blood, and Agnew[8] has been able by this contrast to separate cardiac from chiefly renal involvement. Foster[11] points out that while this holds true

for lesser grades of circulatory embarrassment, it might not prove a reliable criterion in the severest types of purely circulatory disturbance in which nonprotein nitrogen accumulation is not infrequently observed.

Thayer and Snowden[12] make an important contribution from the clinical side. These authors attempt to throw some light on the clinical value of the phenolsulphonephthalein test in prognosis by comparing their findings with the test and the anatomic alterations revealed at necropsy in fifty-four cases of nephritis of different types. In no instance of grave nephritis did they fail to find a material reduction in phenolsulphonephthalein excretion. Their study reveals a progressive diminution in the output of the dye, which they consider so definite as to give the test a considerable prognostic value. They conclude that there occurs in severe chronic nephritis a uniformly low phenolsulphonephthalein excretion, which, as a rule, in those instances not interrupted by an acute terminal process, decreases steadily up to the onset of uremia and is nearly or wholly suppressed from a day or two to a month before death. Acute terminal uremic developments which may be unsuspected clinically are common, and here a sudden diminution in the elimination of phenolsulphonephthalein may come on in cases in which the percentage previously excreted is not so low as to appear alarming. In not a single instance, and, indeed, not once in all their studies for five years, have these authors met with a good phenolsulphonephthalein excretion in a case of severe chronic nephritis. Their observations with the test in twenty cases of chronic passive congestion conform with the findings of Rowntree and Fitz,[13] and they consider it clear that chronic passive renal congestion alone can result in marked reduction of phenolsulphonephthalein excretion, which may return to normal as cardiac compensation is reestablished.

VALUE OF THE TEST

The foregoing discussion briefly reviews the main facts brought out by investigation that furnish our warrant for the employment of this test in clinical practice. Accumulating clinical observation and the fact that results with the phenolsulphonephthalein test in the main parallel the estimation of nonprotein nitrogen of the blood encourage the belief that the findings are, within certain limitations, reliable for prognostic purposes. In interpreting its findings it is to be remembered that the test shows the functional power of the kidneys at the time of observation and for the dye only. The influence of passive renal congestion from cardiac causes is to be borne in mind. If excretory values are low and cardiac insufficiency be not present as a complicating factor, we should not disregard the warning simply because clinical indications of uremia are absent, and, on the other hand, if symptoms indicate danger, their significance is not to be neglected merely because phenolsulphonephthalein excretion approaches normal. Some experience with this test as a routine clinical procedure covering a period of two years encourages me to believe that it constitutes a method of value in nephritis and high pressure states generally. In my observations I have found that excretory response to the test is on the average higher in ambulatory cases tested in office practice than in hospital cases, and this irrespective of the clinical condition present. This is, perhaps, as might be expected, owing to the more general functional decline in patients confined to bed. A comparison of age with functional response would appear to confirm the observation of Miller and Cabot[14] that the excretion of phenolsulphonephthalein grows progressively less with advancing years.

It is extremely doubtful whether the phenolsulphonephthalein test can be employed to any important extent in the diagnosis of nephritis. Routine observations with the method show an output well within normal requirements in the majority of cases classed as nephritis with good cardiac compensation. The latency of chronic nephritis is well known and the inadequacy of clinical observation alone accurately to gage the degree of renal impairment is granted by all experienced observers. Any method that will assist the clinician in obscure cases to arrive at a more accurate knowledge of the organic inroads on kidney secreting structure will consequently be welcomed. It may happen that the renal efficiency test may occasionally prove of service in this direction. Rowntree[15] cites the case of a boy who prior to the function test was looked on as having diabetes insipidus, but who, after one phenolsulphonephthalein test, was recognized as having advanced nephritis verging on uremia, a diagnosis substantiated at necropsy two weeks later.

Recently the test was instrumental in contributing to the better diagnosis of a case under my own observation.

The patient, a young man of robust habit and healthy appearance, complained of cardiac palpitation and vague precordial distress, with a sense of lassitude. Physical examination revealed a moderate degree of cardiac hypertrophy; blood pressure, systolic 160, diastolic 90. The urine was normal in all respects except for the presence of a very few hyaline casts. The best excretion index that could be secured with the phenolsulphonephthalein test was 30 per cent. in two hours. This was interpreted as giving a more serious aspect to his clinically latent nephritis than would have been indicated on clinical and urinary grounds alone.

Perhaps the most important service this test may render us in nephritis is in the diagnosis of obscure uremic conditions. During the course of any case of chronic nephritis there may arise gastro-intestinal, cerebral, visual or other functional disturbances, the uremic nature of which may be strongly suspected. Decisive action is necessary, although clinical grounds may be insufficient for a definite judgment regarding the uremic nature of the symptoms. Without loss of valuable time the phenolsulphonephthalein test will reveal promptly the degree of uremia present.

A type of case that often presents some difficulties in diagnosis is so-called cardiorenal disease. In this condition the blood pressure ranges high, cardiac sclerosis is a prominent factor, and urinary signs signify that the kidneys share in the general arterial involvement. It is not always an easy matter to estimate the relative importance of the cardiac and renal moieties and to decide whether to regard the case from one or the other angle. I have found the renal sufficiency test of assistance in elucidating this point.

[15] Rowntree, L. G.: Am. Jour. Med. Sc., 1914, cxlvii, 352.

My experience with the test would lead me to believe that it may prove of service when employed at periodic intervals in keeping track of the progress of a case and as a more accurate means of watching the effect of treatment than we possess by other means. By applying the test at intervals, the rise and fall in function index forms an interesting and possibly significant chart. How far we can trust the indications gained by routine observation of this sort is difficult to state, but there appears no obvious reason why we should not place some dependence on them. Rowntree and Geraghty report that if surgical patients were given careful preoperative treatment when the elimination of the phenolsulphonephthalein was dangerously low, a marked improvement in elimination occurred. It has been my experience that a steady improvement in the kidney function index may be expected following treatment in cases of nephritis not too far advanced. Mere rest in bed, strict diet and regulation of elimination will ordinarily effect such a result. In advanced cases bordering on uremia, it is rare to observe an improvement following treatment.

A point of possible importance to bear in mind in the interpretation of defective function response in chronic nephritis is the occasional existence of subacute exacerbations. The progress of many cases of chronic nephritis is punctuated by the occurrence of acute inflammatory phases resulting from intercurrent infections or severe kidney irritation. During the existence of such a phase, the excretion of phenolsulphonephthalein may be temporarily reduced much below average figures for the case, and for the time being low values may be observed. A case coming under observation at such a time may appear more grave when viewed from the standpoint of function response than might be justified by the subsequent progress of the case.

General experience with the test has verified the observations of Rowntree and Geraghty regarding the influence of passive renal congestion in interfering with phenolsulphonephthalein excretion. As is well known, contracted kidney cases and cardiorenal diseases generally are, during the later stages, to a large degree cardiac cases, the element of cardiac failure entering to a very important degree into the disabilities of the terminal stage. Broken cardiac compensation as a rule interferes very considerably with the excretion of phenolsulphonephthalein, values well below the safety line appearing with fair constancy along with cardiac edema in chronic nephritis and high blood pressure states. Unless we accord to the cardiac factor its due importance in this regard, we may be led erroneously to anticipate the advent of uremia, and to address our measures of treatment to the kidneys instead of to the heart as they should be.

In view of the clinical vagaries of chronic nephritis, which are notorious, it is perhaps not surprising to meet with glaring inconsistencies in the clinical application of this test. Cases that appear very grave on general clinical and urinary grounds are often found to yield a normal or nearly normal function index, and conversely, instances that appear to be on safe functional ground when judged by purely clinical findings, yield surprisingly low values when kidney efficiency is tested out. Just how we are to strike a balance between the two is often difficult to judge, but in view of the long recognized fact that it is impossible to predict accurately by clinical study alone what course the disease will take in development, it would appear that we should at least accept the results of function study as a qualifying factor in prognosis. It is surprising how long certain cases of chronic nephritis will survive after the excretion of phenolsulphonephthalein is reduced to a mere trace or suppressed entirely; weeks and even months may go by before death ensues after this apparently terminal phenomenon has appeared. No absolute prognosis as to duration of life appears possible on functional findings alone, because we do not yet know how low the phenolsulphonephthalein excretion may go and yet be compatible with a renal efficiency sufficing to maintain life, provided the diet and hygiene of the patient are properly adjusted (Arnold[16]).

DIET THERAPY AND THE TEST

Diet therapy in nephritis is dominated by the principle of protein restriction. Our practice in this important item has hitherto been governed by empiricism without scientific control. So far as can be seen at the present time, the only reliable criterion available for regulating the protein intake in nephritis is the determination of the amount of waste nitrogen retention by blood analysis. That it is possible to reduce the urea waste nitrogen of the blood to normal or less is abundantly proved by the feeding experiments of Folin, Denis and Seymour,[9] and of Frothingham and Smillie.[17] Cases with a considerable retention require a restriction of protein, and by this means a return to normal may be brought about provided the azotemia be not too severe. In case of outspoken uremia no marked reduction of the azotemia results from a protein-free diet. Folin, Denis and Seymour state that the response to the phenolsulphonephthalein test can be reduced by one-half before abnormal accumulation of nonprotein nitrogen takes place in the blood. This estimate is in keeping with Agnew's statement that at 40 per cent., phenolsulphonephthalein excretion, cumulative phenomena appear in the blood. These observations may justify the assumption in clinical practice that when the response to the phenolsulphonephthalein test drops to 40 per cent. or lower in two hours, waste nitrogen blood accumulation is present.

Routine observations with this readily available test may thus enable us to appreciate with greater precision than is possible from clinical observation alone the point (40 per cent. or lower) where positive protein restriction becomes necessary. When the functional index is normal or nearly normal in contracting kidney, it is difficult to understand what harm will result to the kidneys, provided no inflammatory element is present, from a protein ration based on physiologic requirements. Aided by periodic functional testing to check up the functional integrity of the kidneys, and with our present knowledge of physiologic food requirement for good nutrition, the diet therapy of chronic nephritis may be adapted with reasonable safety, if not perhaps with accuracy, and with due realization that in so chronic and widespread a disease general nutrition and kidney conservation should stand on a parity.

THE ORGANIZATION AND ACTIVITIES OF THE INTERNATIONAL HEALTH COMMISSION

JOHN A. FERRELL, M.D.
Assistant Director-General, International Health Commission
NEW YORK

The International Health Commission was created in June, 1913, by the Rockefeller Foundation as its first important act after receiving a charter from the state of New York. Its expressed object is "the promoting of public sanitation and the spread of the knowledge of scientific medicine." Its immediate task contemplates the extension of measures for the relief and control of uncinariasis or hookworm disease to those countries and peoples where conditions invite. This phase of the work is already well under way. Active measures are in progress in several territorial units in the Southern States, Central America, the West Indies, British Guiana and Egypt; and other countries have signified a desire to have the cooperation of the International Health Commission.

In order to give a clear understanding of the plan of organization and the working methods of this commission, I shall review briefly the work of the Rockefeller Sanitary Commission, from which it has developed as a natural outgrowth. The Sanitary Commission was organized by Mr. John D. Rockefeller in 1909, and was granted a million dollars to be used during the ensuing five years toward the eradication of hookworm disease in the United States. This commission was composed of thirteen of the country's leading educators, physicians and business men.

Mr. Wickliffe Rose, executive secretary of the Southern Education Board and general agent of the Peabody Education Fund, was selected as administrative head of the work, with the title of "administrative secretary." Mr. Frederick T. Gates, adviser to Mr. Rockefeller and the chairman of the General Education Board, was elected chairman. As scientific secretary, Dr. Charles W. Stiles was elected. It was Dr. Stiles who discovered the presence and prevalence of the disease in the South, identified as its cause a new type of hookworm termed by him the *Necator americanus*, and did much to center the attention of the profession, the public and Mr. Rockefeller's advisers on its baneful influences.

Mr. Rose opened offices in Washington in January, 1910, and proceeded to organize the work. For obvious reasons the state board of health of each state was selected as the agency through which to undertake the work. Where a health department was weak, he endeavored to aid in strengthening it; and where there was no health department, he sought to help lay the foundations for developing one. The work was always conducted in the name of the state board of health. In each of the eleven states with which the commission cooperated, a state director was appointed by the joint action of the public health authorities and the commission. This director became a state official—an officer of the state department of health—clothed with the powers and responsibilities of the office. He was the organizing and directing head of all the work in the state for the eradication of hookworm disease, and was responsible for results. He worked under the general supervision of the state department; he made reports quarterly to the state department, and through the department to the commission. Under his direct supervision was a force of from three to six physicians as field directors, each of whom was generally assisted by one or two trained microscopists.

On this general plan, eleven states invited and received the cooperation of the commission: Virginia, North Carolina, Georgia, South Carolina, Tennessee, Arkansas, Mississippi, Alabama and Louisiana between February and November, 1910; and Kentucky and Texas in 1912. The remainder of 1910 and a portion of 1911 were devoted to perfecting the state organizations, to educational propaganda, to survey work and to the trying out of working methods.

In beginning the work, the cooperation of the physicians, the educational forces and the press, was successfully enlisted. The educated public soon began to regard hookworm disease as a problem worthy of serious consideration. Working methods were gradually developed on the basis of actual experience under varying conditions. These methods have been growing more systematic, the efforts more intensive and the results more definite.

The work in the beginning consisted very largely in visiting physicians, interviewing them, demonstrating the microscopic technic in recognizing the disease and urging physicians to make examination for its presence a routine in their practice. The essential facts about the disease were prepared in popular form and distributed broadcast over the state—through the newspapers, in leaflets and pamphlets, and by means of circular letters. Lectures to public audiences and to schools were employed as a feature of the work at this stage. Soon, the laity was ready to aid in determining the extent to which the disease prevailed; that is to say, specimens for examination could be obtained with reasonable effort. The state militia was first examined; then children in the various orphanages. When these investigations were completed, and the results published, it was found feasible to have the children in the public schools examined. Squeamishness began to disappear, and the work of examining schoolchildren proceeded rapidly. A group, usually of two hundred children or more, taken at random, was examined in every county, or at least in representative counties. Thus, the prevalence and distribution of the disease were established with reasonable accuracy. In visiting the schools, the field directors also inspected the sanitary conditions of the country homes on the roadside and recorded their observations in each instance.

At this juncture stock was taken. It was observed that the survey work was highly satisfactory. The disease, varying in different localities within the state, and even within the counties, was found to exist among from 10 to 90 per cent. of the people. But the record of cures was small. In December, 1910, Mississippi tried, for indigent cases, the dispensary plan that had worked so successfully in Porto Rico for the whole of the infected population. It was found to be very satisfactory in that state, not only for the indigent cases but also for all who applied. It was soon tried elsewhere, and speedily became in all the states the agency around which the chief activities centered. It provided a means for effective teaching by actual demonstration.

It is still employed in some of the states, which are completing the work with aid from the International Health Commission, in a few of the heavily infected counties that could not be reached before Dec. 31, 1914, which marked the close of the five-year period covered by the pledge of Mr. Rockefeller to the Rockefeller Sanitary Commission. A summary of the work through the dispensaries and through the increased activities of the physicians showed, by the close of 1914, that much had been accomplished in the South in treating the disease. The number of persons microscopically examined was 1,273,850. The number of persons treated and reported was 694,516. Of these, 254,118 were treated and voluntarily reported by the physicians, and 440,398 were treated in the dispensaries.

This county dispensary work was very strenuous for the field forces. County appropriations for local expenses had to be secured; the campaigns had to be advertised and wide interest quickly created. A different dispensary had to be reached every day, often by traveling over miles of rough roads; frequently from one to five hundred people had to be examined during a day, lectured to, the infected ones treated and a complete and accurate record of each case kept. This meant that the men were often out on the day's task from dawn until long after nightfall; but they loved the work and were convinced that the effort was well worth while.

It is to be doubted whether an equal number of men could have been found who would have worked harder, or more effectively, or who would have accomplished so much in the same length of time by any other methods. The population and area to be reached were vast; the funds, and consequently the size of the working force, were limited; the time for completing the work was short, and the county dispensary campaigns were consequently limited to periods ranging from four to eight weeks—a time insufficient to develop satisfactorily the sanitary features of the campaign along with the curative measures.

Obviously, the next development in methods called for a lengthening of the working period; limiting the area to be worked, intensifying the efforts and putting into effect both curative and sanitary measures. This modified plan of work was very satisfactorily developed, during the closing months of the Rockefeller Sanitary Commission, in four states which were early in completing the dispensary work. It was completed before the close of 1914 in twelve communities, each having an area averaging in size about 32 square miles and an average population exceeding a thousand persons (1,025, to be exact). The working period in each averaged about four months. The work was done by a field director, who in some cases was aided by a microscopist. Of the 12,305 persons in the twelve communities, 75 per cent. were examined; 26 per cent. were found infected and 94 per cent. of these were treated and probably cured. Twenty-nine per cent. of them were actually reexamined after a course of treatment and all found to be cured.

In these communities there were 2,257 homes. Fifty per cent. of them in the beginning had no kind of privy, and the privies found were seldom, if ever, sanitary. When the work closed 88 per cent. of the homes had privies, and 81 per cent. of these were of an improved type. The work in some communities was, of course, further advanced than in others. In fully a third of the communities, every family had an improved privy and every person found infected was treated.

This intensive work deserves special attention. It has been carried one step farther by British Guiana. In selected areas of British Guiana there are two staffs at work, under the general supervision of the Surgeon-General. The sanitary staff, financed by the government, enters the area first. It gives the area a thorough cleaning, attends to drainage and enforces compulsory measures requiring every family to provide itself with an approved privy, and to use it and care for it. When this staff completes its work, it moves into another area, leaving in the district a sufficient number of sanitary inspectors, employed permanently by the government, to insure the maintenance of the improved sanitary conditions.

The second staff is medical, and is financed through the local government by the International Health Commission. It aims at the examination of every person in the working area, and the treatment until cured of every person found infected.

This plan insures the development of adequate public health agencies by the government, which will carry on the work after the commission has transferred its aid to other fields, and leaves to the local health organization the enforcement of public health laws. The agency supported by the commission can be temporary, and it depends for its success on the voluntary cooperation of the people. Both staffs have made admirable successes, and there seems much promise that a wider application can be given to the plan.

Return for a moment to the Rockefeller Sanitary Commission. Its work, per se, accomplished gratifying results. Many observers state, however, that the by-products have greatly exceeded in importance the tangible results with hookworm disease as published in the records of the state boards of health, and in the reports of the Rockefeller Sanitary Commission. To give an illustration of this: It was found that the available funds for public health work in the eleven Southern States where aid was given amounted in 1910 to $216,195, and in 1914 to $392,364, an increase of 81 per cent. in less than five years. Of course, the commission does not assume the credit for this increase; it was wholly voluntary on the part of the states. It may be, however, that the states were stimulated by the spirit which pervaded the forces devoted to measures for the control of hookworm disease. At any rate, the health departments are much stronger now than they were five years ago.

One incidental service of the Rockefeller Sanitary Commission to the public health agencies of the South and nation has been the bringing into the field of public health work of nearly one hundred carefully selected young physicians. The large majority of them have acquired a love for the work and an appreciation of the broad possibilities it offers for service to man. More than a third of them have chosen it as a career, and have identified themselves with the state or national public health organizations.

The Rockefeller Sanitary Commission accomplished all that was expected by its founder, and paved the way for the International Health Commission. Mr. Rose studied the work in all the states very closely and correlated it by acquainting all the directors with any significant method employed by any one. His suggestions for increasing efficiency came to the state directors from time to time. They were not imperative. They usually carried by their own force. Occasionally he called the workers together for conferences, when there would be round-table discussions, exchanges of experiences; and usually out of these conferences there developed more effective, more uniform and more systematic working plans.

These fundamental policies which guided the Rockefeller Sanitary Commission are being adhered to in the development of the International Health Commission. They have worked satisfactorily thus far in dealing with a single problem in preventive medicine in the international field. They will probably apply with equal force to other public health problems with which the commission will deal in the course of its development.

Having described the groundwork on which the International Health Commission rests, and outlined the policies which are guiding its organization, I can tell the story of its activities to date in a few words.

In considering this larger work, Mr. Rose in 1911 set to work to collect, from all countries of the world, the available information on the distribution and prevalence of hookworm disease; the extent to which it was a handicap to the health and working efficiency of the people; the agencies at work toward its control; the results secured, and the methods employed. The results of this study were published in 1911. They indicated that the disease prevails in a belt of territory encircling the earth for 30 degrees on either side of the equator, inhabited by more than a thousand million people; that "the infection in some nations rises to nearly 90 per cent. of the entire population"; that the disease has probably been an important factor in retarding the economic, social, intellectual and moral progress of mankind, and that "little or nothing is being done toward its arrest or prevention."

Owing to the time consumed in getting the Rockefeller Foundation chartered, the International Health Commission was not organized until June 27, 1913. The members are: John D. Rockefeller, Jr., chairman; Jerome D. Greene, recording secretary; Wickliffe Rose, director-general, Charles W. Eliot, Simon Flexner, Frederick T. Gates, William C. Gorgas, Charles O. Heydt, David F. Houston, Starr J. Murphy, Walter H. Page and William H. Welch.

In July, 1913, I went to Washington to give assistance in directing the work of the Rockefeller Sanitary Commission and to become later the assistant director-general of the International Health Commission. This relieved Mr. Rose, so that he could make several journeys to foreign countries. He proceeded to London in August on invitation, with a view to establishing work in the British dependencies. The stability of the government and the official use of the English language made them a most suitable field for beginning work. A series of conferences had been arranged for him with groups of scientists, physicians and government officials, the most important, with respect to action taken, being a dinner given by Ambassador Page—himself a member of the commission—August 13. Mr. Rose told, while there, of what had been done in the South, described the plan followed and indicated that the International Health Commission was prepared to cooperate with the British government on a similar basis. The proposition was accepted with eagerness; the government expressed its appreciation, pledged its active cooperation in the work and appointed an advisory committee to assist the commission in the colonies.

The British West Indies appeared to all the logical region for beginning work. Accordingly, Mr. Rose, in October, visited seven of the colonies: Barbados, Trinidad, British Guiana, Grenada, St. Vincent, St. Lucia and Antigua. He desired to make a first-hand survey of conditions. He obtained a general view of the country and established an acquaintance with the officials and the working population. He observed the conditions of infection and discussed working plans with the medical officers. In 1914 he spent about half the year on a journey around the world, visiting a number of countries, giving special consideration to Egypt, Ceylon, the Federated Malay States and the Philippine Islands.

In the meantime, the work of organization had been taking definite shape, and work was getting well under way in some of the colonies. Early in March Dr. J. H. White was secured for a year from the United States Public Health Service to undertake the establishment of work in certain of the Latin-American countries.

Here, as in other places, the commission did not enter the field without first being invited by the government, and receiving assurance of cooperation in the work undertaken. Dr. White had an intimate acquaintance with the Latin-American people, which enabled him to lay the groundwork successfully and develop excellent working forces for Panama, Costa Rica, Nicaragua and Guatemala before the close of his year's work with the commission. These republics will afford nuclei from which operations can spread to the other Latin-American republics as conditions warrant.

In the West Indies, Dr. H. H. Howard is now directing the work. He received his training in the commission's service in the South. On government invitation he aided in organizing the work in British Guiana, which I have already mentioned. Active measures are now in operation or pending for six of the West Indian colonies, and work will be under way within a few weeks in Dutch Guiana. In general, the working plan followed in British Guiana is contemplated in all this field.

The East presents an enormous field for work, which in many respects offers very difficult problems. For this post the commission secured Dr. Victor G. Heiser of the U. S. Public Health Service, who, as director of the Bureau of Public Health in the Philippines during the past twelve years, has dealt successfully with the more or less primitive native population, and developed a highly efficient department of health. He is to give general supervision to the activities previously started in Egypt, and immediate direction to the extension of the work to other countries of the East as conditions favor.

The work of the present year will cost the commission approximately $400,000, which amount is supplied by the Rockefeller Foundation. It is expected that the funds will be increased from year to year with the growth of the commission's work.

I do not know what other fields of activities will be entered by the commission. Measures that now or ultimately may be of international scope would be viewed with greatest interest. You have been told how aid is already given toward the development of public health agencies in several countries. This kind of work will, of course, be continued on one plan or another.

The Director-General has been giving considerable thought to the development of facilities for adequately training workers for the many tasks in the field of preventive medicine. He recognizes also, as very pressing in many countries, the need of facilities for the care of the sick. This field would call for strengthening or establishing medical schools, hospitals and clinics, and the training of natives to operate them. The attack on hookworm disease has led also to the consideration of a similar attack on other diseases, such, for example, as yellow fever or malaria. Entrance into any of these fields, I think, would not be expected except on the basis of careful study and the maturing of definite plans. It might develop that other fields will present themselves which offer more fruitful effort in accord with the paramount aim of the commission, which is to help the countries to help themselves in bringing into activity their own working agencies with their own resources.

INJECTION OF ALCOHOLIC SOLUTIONS OF DIFFERENT STRENGTHS INTO PERIPHERAL NERVES

A COMPARISON OF THE RESULTS OBTAINED *

WILLIAMS B. CADWALADER, M.D.
Instructor in Neurology and Neuropathology at the University of Pennsylvania, School of Medicine; Assistant Neurologist at the Presbyterian Hospital; Clinical Assistant at the Orthopaedic Hospital and Infirmary for Nervous Diseases
PHILADELPHIA

For the treatment of certain kinds of severe neuralgia, intraneural injections of alcohol have achieved much success. Pain can be relieved; but, unfortunately, in order to do so, other disturbances more or less severe may be substituted.

Alcohol destroys nerve tissue by dissolution, coagulating albuminous material and dissolving lipoids. And the extent of destruction must depend on the completeness of contact and the strength of the solution injected. Whenever the sensory fibers of a mixed nerve are destroyed and pain put an end to, motor fibers must at the same time be destroyed and paralysis created, for unlike some other toxic substances, alcohol does not have a selective action on functionally different nerve fibers. In purely sensory nerves like the trifacial, this is of no importance; but in motor and mixed nerves, the sciatic for example, it is of the greatest moment. Strauss[1] has recorded a case in which the sciatic nerve remained paralyzed for a year after the injection of alcohol.

It can readily be appreciated that if a method of using alcoholic injections could be perfected by which the degree of motor paralysis could be greatly diminished without a corresponding diminution in the amount of sensory loss of function, then an almost perfect method for the relief of severe pain might be attained.

The following experiments were begun by Dr. Eisenbrey, in the laboratory of Dr. Charles H. Frazier, at the suggestion of Dr. William G. Spiller, in order to determine and compare the effects of injections of different strengths of alcohol, and the microscopic specimens were subsequently prepared in the Laboratory of Neuropathology.

Seven dogs were operated on. In each instance under ether anesthesia an incision was made and the sciatic nerve was exposed by blunt dissection without disturbing its fascial relations. The nerve was then injected by means of a small hypodermic syringe with the required solution. The nerve sheath was punctured two, three or four times at points close together. The skin incision was closed by suture. After a certain time had elapsed the animals were killed and the sciatic nerves of both sides were removed for microscopic study and comparison. Muller's fluid was used for preservation. Sections were cut in celloidin and stained by the Weigert, hemalum and fuchsin and Marchi methods.

When 80 per cent. alcohol was used, paralysis was immediate and complete; but with 50 per cent. alcohol, paralysis did not appear to be so severe; 25 per cent. alcohol had little or no effect. In one instance 40 per cent. alcohol seemed to cause more disturbance than did a 50 per cent. solution.

These results were substantiated by the microscopic appearances of the nerves themselves. In every case paralysis was caused by the direct chemical action of alcohol, which invariably resulted in nerve degeneration. With 80 per cent. alcohol degeneration was practically complete, but 25 per cent. alcohol did not cause any definite changes from the normal. With 50 per cent. alcohol, degenerative changes within the nerve were very distinct, but somewhat less pronounced than those caused by 80 per cent. solution.

In no instance did salt solution injected into the sciatic nerve cause any evidence of degeneration, or any clinical signs suggesting paralysis.

The mere technical procedure of inserting the needle did not produce any disturbance, hemorrhage did not occur, and scar tissue did not develop at the site of injection; nor was perineuritis sufficiently marked to be of importance.

In drawing deductions from the facts presented, it would seem proper to conclude that strong alcoholic solutions cause greater destruction of nerve tissue than very weak solutions, and that salt solution may be entirely harmless. The nerve fibers were entirely destroyed by the stronger solutions, yet they appeared in a favorable condition for ultimate regeneration and recovery of function.

In general these results are in harmony with those obtained by May.[2] In his Group 1 the results were rather variable. Thus, in his Cases 11 and 14, the injection produced no obvious effects, but in Case 12 a slight transitory weakness ensued, while in Cases 9, 10, 13, 15 and 16, the disturbances of function were very severe and lasting. However, in Case 11 he used only 50 per cent. alcohol, and in Cases 9 and 14, 90 per cent. was used. May believes that such great contrasts must depend largely on the difficulty of ensuring adequate penetration of the nerve by alcohol. No doubt this is true; nevertheless, stronger solutions are much more destructive than weak ones, provided the technic is adequate.

There is abundant clinical evidence to prove that after destroying the nerve by injecting alcohol, regeneration and restoration of function does occur, provided complications do not interfere.

Schlosser,[3] after having treated 209 cases of neuralgia, expressed the opinion that cures by this method were not permanent, but afforded freedom from pain for about a year. In 123 of his cases, the trifacial nerve was affected, and among these there was an average of ten and a half months' relief from pain.

My experiments do not warrant any conclusions in regard to the length of time required for regeneration; all that can be said is that the nerves appeared to be in a favorable state.

When a nerve has been severed and reunited, a number of months may be required for restoration of function; indeed, many such cases are recorded in which the conditions appeared to be favorable, yet more than a year elapsed before recovery took place; but it would seem probable that nerves destroyed by alcohol should regenerate at least as quickly as when severed by some other means; in fact, they might regenerate more rapidly because their sheaths would not have been disturbed, and the likelihood of scar tissue developing would be diminished. In most of Schlosser's cases, recovery of function seems to have required about ten and one half months.

In Greeman's[4] experiments on rats, he found that when the sciatic nerve was cut, so much scar tissue formed that regeneration was interfered with; therefore he destroyed the nerve by crushing, by this means preserving the nerve sheath, which served to exclude fibrous tissue, and regeneration was not interfered with. It is not improbable that in some instances the mere mechanical interference of inserting a needle might lead to scar tissue formation or hemorrhage. This might account for the permanent paralysis which occurred in a case mentioned by Bassoe.[5] In so large a nerve as the sciatic there are blood vessels of considerable size relatively, and if injured, hemorrhage might occur sufficient to cause paralysis. In such a case surgical interference should be considered, for if sufficient time for regeneration had already elapsed, there must still be some local disturbance, which might be successfully removed if the sheath of the nerve trunk could be opened.

Facial spasm can be stopped by injection of the stronger solution of alcohol, but of course paralysis must be substituted. It would seem that in such cases repeated injections should be tried, first beginning with 25 per cent. alcohol and then gradually increasing the strength; by this means spasm might be relieved and the paralysis which is substituted would be made less severe and of shorter duration.

The Industrial Proletariat.—A century and a half of the new economic system of production has passed and has inevitably brought about profound changes in the industrial and political development of the civilized world. During this period, giant strides have been made in industrial expansion, and wonderful discoveries in the domain of the physical sciences. Invention has been followed by invention, and greater economic progress made within this comparatively short period than during the whole history of mankind. Methods of production have been completely revolutionized and industrial control concentrated in the hands of a special class; while a large portion of the population has been converted into a great standing army of a new class—that of the industrial proletariat.—Price, the *Modern Factory*.

RELATION OF THE GENUS "MONILIA" TO CERTAIN FERMENTATIVE CONDITIONS OF THE INTESTINAL TRACT IN PORTO RICO *

BAILEY K. ASHFORD, M.D., Sc.D.
Major, Medical Corps, U. S. Army
SAN JUAN, P. R.

Throughout the last six years I have had an opportunity to observe more closely the large number of indefinite symptoms which make up what has been variously termed by us neurasthenia, anemia, chronic gastritis, gastro-intestinal catarrh, fermentation in the intestinal tract, fermentative dyspepsia, chronic gastroenteritis of the tropics, *descomposiciones del intestino*, culminating in such diagnoses as gastro-enteritis tropical, phthisis intestinal, and sprue.

Fully one-half of my own personal experience has been with those who suffer from what our patients are pleased to denominate "the stomach," meaning, nine times out of ten, the intestinal tract. The complaint usually is that they cannot eat without bloating; that, from time to time, they have "decomposition of the bowels"; that they are getting pale and losing strength in spite of what they eat—all trying to overfeed in the hope of strengthening themselves. To this add the very large number who have, in addition, vague pains in the "kidneys" and the rest of the body, who become breathless on the slightest exertion, and who are extremely nervous. It has been entirely impossible for me to deny the self-evident fact that from the rank of these people come the majority of our cases of true sprue, as so described, with its four cardinal symptoms—sore and beefy tongue, a gaseous bowel, a foamy, light-colored, abundant diarrhea, and a small liver. It has been entirely impossible for me to dismiss the suspicion that sprue, as we know it, is usually only the terminal phase of that which we have so frequently seen in our offices, and which we have contented ourselves heretofore in calling "fermentative dyspepsia," or any other descriptive term which seemed scientific and medical.

The strife which has taken place to determine the cause of that most fatal disease, still known by its Dutch name of sprue, has led men all over the world to variously consider it here a condition, there a disease; here due to a protozoon, and there to a fungus. Of late this strife has become acute and some men are boldly asserting that no one has proved even that sprue is a disease.

Several years ago I had about concluded that sprue was a disease and that it might be due to some parasite carried in certain fruits, particularly the pineapple. That was because a good many of my patients at that time, representing my worst cases, came from fruit-bearing districts. Then, unable to find anything definite in the pineapple theory, I began to believe that sprue was a disease like beriberi, considered to be an intoxication; but after taking careful histories, my suspicions rested more and more on the yeasts. With this strong suspicion in my mind, I received one day from Mr. John M. Turner of San Juan, a pupil of Doremus, and a man who is very practical in his judgment of the value of flour and yeasts, a letter in which he said that he believed that something was the matter with the yeast here, and he connected it in some way with sprue. Later on I was attracted to examine the tongue of a child 12 years of age, suffering from what appeared to be thrush. On culture, however, the organism did not ring true to what I had read of *Oidium albicans*, and from that time I have steadily devoted myself to the study of mycology as it applies to sprue. To Chalmers and Castellani is due the credit of furnishing a means by which we can distinguish between the various species of "Monilia," understanding that Monilia is a yeast-like body producing mycelial threads in its vegetative state in contradistinction to its congener, with which it has heretofore been confounded, saccharomyces, which reproduces in its vegetative condition by ascospores.

---

* Read before the Medical Society of the District of the North of the Porto Rico Medical Association, March 18, 1915, by the author as president of a board for the study of tropical diseases as they exist in Porto Rico, and collaborating with the Institute of Tropical Medicine and Hygiene of Porto Rico.

Up to the present, since October, 1914, I have made cultures in Sabouraud's glucose agar, 4 per cent., plus 2, from 100 tongues. I consider this medium as specific for Monilia as Loeffler's blood serum mixture is for *Bacillus diphtheriae.*

Twenty-two of these cultures were from cases of typical complete sprue, with actively inflamed tongues and with frothy diarrhea at the time of examination, and all were positive for Monilia at the first examination. Three of these patients have since died. This gives a percentage of 100 harboring Monilia in this group.

Forty-seven either had been cases of sprue under my care or had histories, present or past, which were more or less suggestive of it. All save 7 of these had normal tongues at the time cultures were made. Of these 47 cases, 10 gave positive cultures for Monilia, 7 causing, if we accept moniliasis as the new term for sprue, the intestinal, and 3 the tongue type. Of the 7 which had inflamed tongues in this group, 3 were clearly cases of tongue sprue. The 4 negative were as follows:

A baby, aged 4 months, with simple stomatitis of brief duration (four days).

A teething, rachitic child of 18 months, with a severe enterocolitis.

An old man with chronic enterocolitis.

A young man, father of one of the three patients with tongue sprue positive for Monilia, one of this series of 47.

(Only one tube was inoculated, and with another effort the parasite might have been demonstrated.)

The percentage of cases positive for moniliasis of the tongue was 21.

Thirty-one persons were examined who did not have sprue. Twenty-six had no suspicion of sprue, past or present, and had normal tongues. Only one of this class was positive for Monilia. This case was one of a pale man who at first gave no past history of fermentation disturbance of his bowel, but who later recounted a history most suspicious of sprue of the intestinal type. His wife had active, complete sprue, and belongs to the first group.

Of the 47 cases suspected of sprue, the feces of 4 negative by the tongue were examined and 3 found positive. The remaining 33 are still to be investigated in this sense. Three of the 47 cases suspected of intestinal sprue on cultures from their feces were positive.

In all, the feces of 10 of the 100, and one other, were plated and only the 3 above noted, and one of Series 1 already positive for his tongue lesion, were positive. Three of the remainder were cases of pellagra. The other 3 were from healthy persons.

RESULTS OF TREATMENT

Treatment consists usually in the administration of food in which Monilia does not flourish, and which it cannot ferment. There are three types of diet:

1. A strict milk diet, giving 8 ounces every two hours on nine occasions a day for four days, and thereafter increasing the dose by one ounce every four days until 13 ounces every two hours have been taken for one week. The milk should be taken cold through a straw, slowly, and half a culture tube of the liquid culture of the Bulgarian strain of the *Bacillus acidus lacticus* should be added to each feeding, for the purpose of overgrowing bacterial sources of fermentation. On reaching a dose of 13 ounces of milk, one banana a day should be added, and every four days one more for every ounce of milk to be subtracted per feeding. When 10 ounces of milk every two hours and three bananas a day are reached, the diet may be modified by gradually permitting eggs, fruits and fresh vegetables with a low carbohydrate content. After a few days on this diet the excess of gas usually diminishes; indeed, generally disappears.

2. A strict meat diet, giving 2 pounds of chopped and roasted meat per day, divided into six feedings three hours apart. Few can sustain this diet over a week, but almost without exception it stops the diarrhea. (Carnegie Brown.)

After this week add vegetables, fruits and eggs as above, and reduce meat.

3. A simple fruit diet in which bananas may form the principal feature.

Of this series of sixty-nine cases of sprue and fermentation conditions of the bowel or simple stomatitis, 12 were cured, 32 have improved, as a rule greatly, with gain in weight and color, 19 are still not sufficiently changed to warrant deductions, 2 have become worse, 4 have died.

I regret to state that continued experience with santonin and emetin has long since caused me to abandon their use because of their inefficacy.

The organism is a typical Monilia. Its biologic characteristics are that it ferments glucose, levulose and maltose; that it causes an acid reaction in these three, and in saccharose and galactose; that it does not liquefy gelatin or serum; does not coagulate or render milk acid, but on the contrary, renders it alkaline; and that all other sugar mediums lose rapidly in acidity. In pure culture, five drops of it were injected into the muscles of the tongue of a large Belgian hare, causing its death in seventy-five hours thereafter, with enormous production of intestinal gas and diarrhea, but without sore tongue, the identical organism being recovered in pure culture a few hours after death directly from practically all of the organs of the hare's body.

The same organism—which, by the way, was one isolated from the tongue of one of our most beloved officials of the American government here, and which not long since caused his death—was fed in pure culture to a one-thousand gram guinea-pig, causing, I suspect, its death three weeks thereafter. Cultures from the organs of the body, save tongue and stomach, however, were very disappointing, and the histopathologic picture in its intestines and stomach has not yet been worked out for lack of time. This animal also suffered from gas and diarrhea. Cultures of this organism with malted milk were fed during a time to a monkey. This monkey is still alive, but, although the feeding experiments have been stopped now about three weeks and the animal is being fed good rations, it having previously been fed on malted milk mixed with the culture, it is rapidly declining in health, becoming thin and sick, with occasional sharp diarrhea. The last word must yet be said on this animal.

To sum up, animal experimentation seems to bear out in a general way that we are dealing with a pathogen of low virulence and that we cannot expect to obtain any sensational sudden deaths from acute sprue due to feeding experiments, if, indeed, we shall be able to satisfy the scientific world that Monilia has been the determining factor in the death of any animal fed by its cultures.

What I particularly want to bring out is the suggestive evidence presented by the examination of what now is a considerable number of tongues, of cases of sprue and those not sprue.

Bahr's conclusion that *Monilia albicans* is the cause of sprue in Ceylon requires some comment in this paper. With his reasons for and against considering sprue to be a moniliasis of the digestive tube, and his conclusions therefrom, you are now familiar. The conclusions drawn are the result of an interesting study of sprue in Ceylon for two years by a most distinguished group of English workers, and cannot be lightly criticised. Nor are we authorized to question their findings. But the work here demonstrates that the Monilia of sprue in Porto Rico is *not Monilia albicans*, but an organism which has not heretofore been described. For the rest, Bahr's reasons for considering sprue to be a moniliasis of the intestinal tract are remarkably strengthened by the work here. Bahr states that he has found Monilia in 57 per cent. of sprue tongues and 17 per cent. of normal tongues. I have found them in 100 per cent. of sprue tongues and 3 per cent. of normal tongues. If you care to add my seven cases of intestinal sprue with normal tongue, the percentage would be raised to 11, but this is not fair, as it would deny that the seven were intestinal sprue.

I have not yet found *Monilia albicans* in Porto Rico, nor does any one seem to have described my species in temperate climates. Hence, Low's chief criticism of Bahr's work, in which he practically denominates it a failure to prove the cause of sprue, certainly does not obtain here. This distinguished worker objects that a Monilia common in England without sprue could cause sprue in Ceylon. It is well answered by Bahr, who notes that regional influences may greatly affect identical organisms and make of pathogens of almost no virulence, very dangerous parasites. As to Low's objection that the geographical distribution of sprue is in favor of his and Castellani's protozoa theory, let me say that we do not at all know the distribution of sprue, even clinically, because little has been written of it and a diagnosis is often difficult.

May not some of the pellagra of our Southern states be in reality sprue? It would be interesting to study some of the cases without skin lesions in which the diagnosis is pending between these two diseases. I have had so far three cases with stomatitis and white diarrhea which I considered sprue without moniliasis of the tongue, but which later cleared up by the appearance of the pellagrous eruption.

While fully aware that it will be some time—perhaps many years—before the sum total of circumstantial evidence will point to Monilia as the unmistakable cause of sprue, I wish to state my belief that sprue is moniliasis of the digestive canal, and that in Porto Rico, at least, it is due, so far as I have yet gone, to the species which I have recently described in the course of work in the Institute of Tropical Medicine and Hygiene in Porto Rico.[1]

I have found other monilias in the stool, which are still under study, but the examination of tongues seems to point overwhelmingly to sprue tongue as being caused by the Monilia I have described, and from a sprue tongue to intestinal sprue is only a matter of extension. It is difficult to conceive how a protozoon could be affected by the treatment which has been found to be the sine qua non for the cure of sprue, namely, the withholding of those articles of food which in my cultures of Monilia are proved to favor its growth and cause fermentation and acidity. In fact, apart from the remarkable consistency of my Monilia in sprue tongues, and its usual absence in uninflamed tongues, to me the therapeutic test is the most striking, for any one can take a case of sprue and, almost without exception, after an appropriate diet of milk, meat or fresh fruits, or a combination, can dismiss inflammation of the tongue, gaseous distention of the bowel, diarrhea, and even, if you please, much, if not all, of the cachexia. Is it not more than a coincidence that the withholding of carbohydrates is enough to cause an immediate betterment, for the time being at least, and generally, a temporary "cure" of sprue, which perhaps may be permanent? The very fact that some cases are permanently cured by these diets alone, without any medicine whatsoever, makes me extremely suspicious of the asseveration of Chalmers and Castellani that sprue is not likely to be a "mycosis," but is probably a protozoal disease.

In conclusion, I wish to call attention to the fact that I am now engaged in studying cultures from the excrement of persons affected with fermentative conditions of the intestinal canal in Porto Rico, and am finding with great regularity monilias which seem to correspond, in the few mediums I have sown, with those I am finding in true sprue, not forgetting that it is more than possible that in this dangerous genus Monilia there must be more than one pathogen for the intestinal canal. One must ever keep in mind that the clinical signs and symptoms of sprue depend largely on the portion of the intestinal tract affected, an observation well brought out by Bahr. Thus, tongue sprue is called *Sapito,* or thrush, here. It is common among children, and often is followed by a picture impossible to avoid denominating sprue. But many such cases promptly get well, and an incredulous smile is the only reward for suggesting that such cases of "thrush," frequently of long duration, but strictly limited to the tongue, are really local sprue. I have a little patient who for six months suffered from tongue sprue alone, positive for Monilia, and utterly rebellious to all treatment so far employed, but some months previous to his tongue symptoms he had a three months' bout of white, frothy, abundant diarrhea without mouth symptoms. I have another such case of short standing, in a patient who was taken suddenly ill with fever of 40 C. and a fiery red and desquamated tongue. She was a young school teacher and gave a history of occasional gaseous disturbance of the bowels with frothy movements. No diarrhea, however, accompanied her tongue sprue. In fact, this oscillation from simple tongue sprue to intestinal sprue and back again is typical of sprue. Whether there is more than one species of Monilia that causes sprue remains to be seen, but the matter is one of vital importance, and every effort should be made to assist the Institute of Tropical Medicine in investigating all cases in which the diagnosis of sprue has or should be made, to determine the presence or absence of monilias.

---

[1] Ashford, B. K.: A Monilia Found in Certain Cases of Sprue, THE JOURNAL A. M. A., March 6, 1915, p. 810.

I cannot close this paper without requesting that some systematic effort to examine the bread in this island for the presence of Monilia be made. I have found living Monilia in the center of a cooked loaf of bread, underbaked, of course. With my colleagues of the Institute, we examined 10,140 country people in the mountains of Porto Rico last year for clinical evidences of sprue and were only able to obtain nineteen cases, some of which were even doubtful, while in San Juan I have seen over 300 cases in six years, and I know you all have had many cases. When we consider this and think also that country people in Porto Rico, such as live in the mountains and in distant barrios—such, in short, as form our clinics in the mountains—rarely eat bread, and that out of the nineteen cases eleven were from the town of Utuado, there is another reason why we should fear Monilia infections of bread—if not fear, at least investigate—for the matter is becoming actually vital to the life and health of many people who are willing and able to spend the money to keep in good health.

INDICATIONS FOR OPERATIVE INTERFERENCE IN GOITER

V. P. BLAIR, A.M., M.D.
Fellow of the American College of Surgeons
ST. LOUIS

If, in the present state of our knowledge of the clinical manifestations of goiter, we undertake to operate on others than those that are unquestionably causing immediately grave, evidently correlated detriment, a very nice discrimination must be exercised. In young people it is probable that most of the enlargements are more or less physiologic, an effort to meet an increased demand; here if any treatment is indicated it certainly should not be of a destructive kind.

The real or fancied presence of a goiter is rather common. Even more common are individuals who are out in their functional adjustment; the neurasthenic, the highly strung person suffering from mental or physical overstrain, the early phthisic, or the patient suffering from any one of a number of chronic intoxications; many of these give a picture that may more or less closely resemble thyroid intoxication or irritation, and these individuals may have a coincident goiter. If, on the other hand, we are content to deal surgically only with those that are unquestionably responsible for imminently dangerous conditions, then we shall miss the most opportune time for effectively treating many that are causing real, progressive damage, the seriousness of which will later have become much more evident: as a general rule, the more evident the damage the more danger in the operation and the less satisfactory will be the result. The real degeneration caused by goiter can only be checked, not repaired, by the removal of the goiter.

For practical purposes, goiters may be considered to do damage in one or both of two ways, by mechanical pressure or by intoxication. In using the term "intoxication" I know I am somewhat begging a question, but I use it as a matter of convenience to avoid prolix discussion. Either the pressure or the intoxication may be very acute, or it may be very insidious but none the less detrimental in the end.

Goiters that seem to poison the patient have been grouped together under the terms of "toxic" or "exophthalmic" goiters, while goiters that do not produce toxic symptoms have, regardless of their histology, been classed as simple goiters. Kocher has pointed out that not all toxic goiters are of the same nature. H. S. Plummer,[1] seconded by Wilson's[2] histopathologic studies based on clinical and histologic analysis of a large series of operated goiters, have subdivided the toxic goiters into true exophthalmic and toxic simple goiters; the former show mental stimulation and sympathetic phenomena and histologically show true hyperplasia in some part of the gland, while 50 per cent. of them will show exophthalmos. According to their statistics the toxic, simple goiters never develop exophthalmos, and differ in other respects clinically from the true exophthalmic goiters and do not show hyperplasia. Since they have published these studies, we have been able to foretell whether the histologic examination will show the presence or absence of hyperplasia with sufficient constancy to lead me to accept this subdivision as a definite step forward in the unraveling of goiter pathology.

In dealing with them clinically, we divide goiters into five groups:

1. True exophthalmic goiters.
2. Toxic, simple goiters.
3. Nontoxic, simple goiters that are not causing demonstrable damage and are apparently not liable to.
4. Simple goiters that from their size, location or growth tendencies are liable to cause obstruction or might be malignant, and those that are actually causing obstruction.
5. Inflamed goiters.

To these five groups might be added a sixth, malignant goiters, were it not so very difficult to distinguish them clinically, while they are still operable, from simple nodular goiters in which operation is definitely indicated on account of some peculiar growth characteristic.

Kocher long ago came out flat footed with the contention that excision of one half of the thyroid was the proper treatment for an exophthalmic goiter, and advanced medical thought has slowly swung around to accepting, tentatively, the correctness of this principle. There are those who treat certain exophthalmic goiters medically and successfully, as they treat certain cases of appendicitis in the same way; but this does not gainsay the propriety of the operative plan of treatment.

The premise on which exophthalmic goiters are subjected to operation is that in some way the goiter mass is related to the clinical symptoms and that reduction in the amount of the mass will reduce the intensity of the symptoms. This does not mean that the intensity of the symptoms bears a direct relation to the size of the goiter, for a large goiter in one individual may be much less toxic than a small one in another person, and the toxicity or the susceptibility of the individual may vary from time to time without material change in the size of the gland. What I do mean is, if in a given exophthalmic or even in a simple, toxic goiter at a given time a certain amount of the gland is removed or put out of commission, there will be a proportionate reduction of the toxicity. For reasons to be given later, the clinical evidence of this reduction of toxicity is not always perfectly plain.

---

[1] Plummer, H. S.: Am. Jour. Med. Sc., 1913, cxlvi, 790.

[2] Wilson, L. B.: Am. Jour. Med. Sc., 1914, cxlvii, 344; Relation of the Pathology and the Clinical Symptoms of Simple and Exophthalmic Goiter, The Journal A. M. A., Jan. 10, 1914, p. 111; Journal-Lancet, Feb. 15, 1914.

Along with our ability to reduce the intoxication by the removal of part of the goiter, we should not lose sight of the other equally important clinical fact that the toxic stage of an exophthalmic goiter has a distinct tendency to crisis and self limitation. If this is so, why operate on them? For the same clinical reason that we will operate on a diseased appendix; to reduce the direct death rate which under any treatment is not very large in either of these diseases, and also, which is more important, to reduce the period of chronic disability and to prevent the permanent damage which may result when the disease is not completely cured. That the general results of operating for exophthalmic goiter are not so brilliant or so evident as those for appendicitis may be due wholly or partially to one of the following three causes:

First, a certain percentage of cases have been operated on a mistaken diagnosis and never were cases of goiter intoxication.

Second, a case presenting goiter, exophthalmos, tremor, rapid heart and nervous derangement is not necessarily a case of present goiter intoxication; these may all be evidences, more or less, of permanent damage in a goiter that has run its toxic course, and has ceased to be active. It is reasonable to suppose that in such a case no amount of thyroid reduction will repair the damage. An old Pennsylvania mountain practitioner once designated them as "burnt out goiters," and whenever I observe one of them, I am reimpressed with the aptitude of the simile.

Third, a common cause of only partial success is the removal of an insufficient amount of goiter tissue, and yet in the very case that is apparently so disappointing, you may have accomplished your chief object, namely, the saving of the patient's life. This point has been aptly illustrated by comparing a goiter toxemia to alcoholic intoxication. We will grant that in two certain individuals a quart of whisky would be lethal, and that a pint would not be. Then if those individuals were to swallow a quart of whisky each, and one of them vomited half of his dose, for a time both might be apparently equally drunk, but in the end one would recover and the other would die.

This point, ingeniously expounded by Plummer, is illustrated in the following hypothesis: Suppose if in a certain case of exophthalmic goiter it were left unoperated, a fatal crisis would have occurred in the ninth month of the disease, yet in the fourth month the patient shows only a moderate amount of intoxication. If in the fourth month half of the thyroid is removed, it is perfectly conceivable that the intoxication may be greater at the ninth month, the height of the crisis, than it was at the time of operation, and still this patient's life may have been saved by operation.

Halstead[3] reported thirty-nine cases with successful results, in which the greater part of both lobes of the thyroid were removed at two or more operations, in patients who had not been cured by the excision of a single lobe, and in some of them three arteries had been tied. My own experience with secondary excisions has been equally satisfactory, but I now try to avoid them, whenever practicable, by excision of one and one-half lobes at the first operation. Much is supposed to depend on the postoperative care which the patient receives, and in practice this phase should never be neglected; but I feel rather satisfied that if sufficient gland has been removed, the postoperative care will be of less importance.

The most valid objection that can be raised against radical operation for exophthalmic goiter is that the operative mortality which is almost inseparable from operations in these patients in inexperienced hands, which is the early part of any series, unless the operator has been fortunate in his training, is apt to be most discouraging. Most exophthalmic goiter cases come to, or are referred to, the surgeon in or near the height of a crisis, and at this period a radical operation is only too apt to be fatal. However, these patients can usually be nursed along and the crisis bridged over by rest, the use of galvanic current, and one or more ligations, to a stage when the operation can be performed with sufficient safety to be good surgery. Some patients will die after a single ligation, but these deaths are to be charged to the disease, and not to the surgery. Plummer has told me that he has seen more people die of exophthalmic goiter within the first three days after their arrival at Rochester, than have died there postoperatively from goiter excisions. In doubtful cases, preliminary ligations give a very good index to the patient's ability to withstand the radical operation.

The thymus gland is apparently always enlarged in exophthalmic goiter. For a long time, especially in Germany and France, numerous men have contended that in a certain proportion of cases the thymus, and not the thyroid, is the chief factor, and some partial thymectomies have to be done. There has not been sufficient clinical experience to prove or disprove this contention, but rather a definite picture has been described as belonging to thymic cases. Lately Halstead[4] has come out in support of this view. In the hope of obtaining more light on this particular phase of the subject, in relation to certain of our own cases, I recently made a visit to Rochester, Minn., to learn the views at the Mayo Clinic. Plummer said that he had not seen sufficient evidence to warrant the distinction. Judd, after talking to some French visitors, said that he had been tempted to resect the thymus in a certain few cases but had not done so. As far as I know, Kocher has not conceded a major rôle to the thymus in exophthalmic goiter, but has regarded excessive enlargement of the thyroid with glycosuria and nephritis as an advanced and inoperable stage of the disease. I believe that at present this phase must be regarded as an open question. Of my own patients, referred to above, who in some way resembled the pictures described by those who believe the thymus to be a possible major factor, two had thyroidectomies done last summer, and one a double ligation. The late reports from these thyroidectomies would indicate that, for the present at least, they are in need of no further surgery. The ligation case is now ready for a thyroidectomy.

---

[3] Halstead: Excision of Both Lobes of the Thyroid Gland for Graves' Disease, Ann. Surg., 1913, lviii, 178.

[4] Halstead: Bull. Johns Hopkins Hosp., August, 1914.

Toxic simple goiters are to be treated by excision or enucleation of the more evidently diseased part of the gland. In these, there is apparently no danger of postoperative hyperthyroidism, but these patients may die postoperatively on account of the advanced degenerative changes that have developed during the period of intoxication. Results of radical operation in these cases are usually excellent, but often great care must be exercised in the diagnosis. That a patient has a goiter is not in itself sufficient reason for assigning accompanying nervous or cardiac symptoms to the goiter as a cause.

Whether or not we accept the hypothetic distinction between exophthalmic and simple goiters cited above, it has no real bearing on the question of the operative treatment of toxic or exophthalmic goiters as a class; but I believe it does give the surgeon some further guidance in the prognosis and in the selection of a particular mode of procedure in a particular case.

Of the nontoxic simple goiters, probably only the ordinary adolescent and certain nondegenerating colloid goiters are amenable to medical treatment; but unless one took the extreme view that because a certain proportion of simple goiters will later show toxicity or cause obstruction, or become malignant, all should therefore be removed; this does not mean that all simple ones require surgical treatment. A very few during adolescence will require operation; a few of them will be of the exophthalmic type, and even here conservative operation may suffice. There is no evidence to show that adolescent, simple goiters are in any way related to the simple ones of later life; and until such evidence is forthcoming they will not be operated on except in special individual cases. Occasionally they are resected on account of their size, but this is a rare occurrence, though Kocher states that goiters of pronounced irregular growth should be removed regardless of age. Many adults carry simple goiters through life without inconvenience or symptoms. Simple goiters causing no symptoms may demand removal on account of their size. The ease with which a single nodule or cyst can be enucleated may decide the removal of those of but moderate size. Goiters causing pressure symptoms, including those interfering with the recurrent nerve, rapidly growing goiters, those situated in the chest or behind the pharynx or trachea, tender goiters and those causing spontaneous pain should receive surgical treatment, which usually consists in the removal of the more evidently diseased part of the gland with the preservation of sufficient functioning tissue. As a general rule, nodular goiters are more apt to require thyroidectomy enucleation or resection than the smooth homogenous ones.

Simple thyroiditis is seldom, but suppurative thyroiditis and acute and chronic strumitis are usually helped by proper operation. This may consist in simple drainage, excision of a lobe or enucleation of a calcified nodule or suppurating cyst.

Malignant goiters, if movable, should be removed; but the diagnosis of malignancy in operable goiters is usually made after their removal.

Before undertaking any goiter operation, it should be determined that the general condition warrants the surgical risk. Even in simple goiters of long standing, this may require nice discrimination on account of the extent of the secondary degeneration present in vital organs.

Judd has made some interesting observations in regard to goiter in pregnancy. If exophthalmic goiter develops during pregnancy, either death in crisis or spontaneous recovery is apt to occur toward the end of the pregnancy. Patients operated on during pregnancy, other than by simple ligations, are apt to miscarry a month after operation, and to be extremely ill or die. This has happened when it was not known that the patient was pregnant at the time of operation.

In the presence of real hyperthyroidism, none but absolutely necessary excisions for relief of pressure are indicated.

SUMMARY

Toxic simple goiters and exophthalmic goiters that are still active are entitled to some sort of operation that tends to lessen the bulk or activity of the gland.

Adolescent goiters, with rare exceptions require no operation.

Simple goiters are to be dealt with according to the indications of the individual case.

Pregnancy greatly increases the risk of radical goiter surgery.

Metropolitan Building.

THE PRESENT STATUS OF THE ABDERHALDEN TEST [*]

FREDERICK HOWARD FALLS, S.B., M.D.
CHICAGO

Much has been written in the last two years on the Abderhalden test. The workers in this field may be divided into three groups:

1. Those who support Abderhalden's contentions entirely and believe that a diagnosis of pregnancy, carcinoma and various other conditions can be absolutely made by exposing the serum from a case to the specific substrate against which these ferments are mobilized by the body.
2. Those who believe that the method is of no possible value in diagnosing pregnancy or any other condition.
3. Those who believe that, while the ferment content of the blood is undoubtedly increased in pregnancy and various other conditions, the specificity of the ferments as maintained by Abderhalden and his supporters is not proved as yet; and in the light of the most recent work is highly improbable.

To the individual not engaged in the work, the many papers appearing, some of which contain contradictory statements, must be very confusing. It is in the hope of clearing up some of this confusion by a statement of what has been found recently by other authors as well as by the writer, that this paper is offered.

In the first place, Abderhalden's present position must be of paramount importance. Since the first descriptions of his technic appeared, various slight modifications have been advised by him. For example, he advises a longer period (from twenty to twenty-four hours) for dialyzation.[1] Why, may we ask, if, as he states, he has never obtained an incorrect result with the shorter dialyzation period, does he advocate this change? Furthermore, why is the limit of dialysis put at twenty-four hours? If the ferments are strictly specific, no digestion would occur in the longer dialysis period. The obvious answer to these queries is that he failed to obtain positive reactions in true cases of pregnancy when dialyzing only sixteen hours; and he obtained positive reactions in cases not pregnant when dialyzing more than twenty-four hours. These results are exactly in accord with my own, and with those of others. However, this point is not set forth in Abderhalden's writings or in those of his associates. Moreover, Abderhalden arbitrarily insists that a reaction which contradicts the clinical findings must be due to error in technic and that one must find such error to explain the apparent discrepancy. This is practically an admission that the reaction is not infallible, and that search for the cause of the failure must often be made after the clinical diagnosis is apparent in a given case.

---

[*] From the Departments of Experimental Medicine and of Obstetrics, University of Illinois, College of Medicine.

[1] Abderhalden, E.: München. med. Wchnschr., 1914, lxi, No. 8.

From the workers in this field in this country whose papers appeared in the early months of last year, and who then enthusiastically endorsed Abderhalden's assertions, we have heard very little in the later months. I have determined by personal communication in some instances that their early results were not borne out by their later experiences, and that in several cases the test has been given up entirely because of its unreliability.

The men who are still supporting Abderhalden's assertions as to the absolute specificity of the ferments and reliability of the test are either relatively new workers in this field of serology, or men connected with a commercial laboratory.

Of the second group of men, those who deny that the test has any value, that there is nothing to show that the ferments are increased in pregnancy and other conditions, little need be said. They demonstrate by their statements that either they have not done enough work with the test to know whereof they speak, or that their technic was so poor that they could not obtain results with any test requiring a knowledge of serology.

The third group of men believe that the ferments are increased in these various conditions; that there is no proof that these ferments are specific, and that the Abderhalden test may be of value as an aid to diagnosis in a given case, but that it is not by any means infallible. Most of these men, including myself, consider that a negative reaction in a doubtful case is of more value in ruling out pregnancy than a positive reaction would be in affirming it. This view was put forward by Echols[2] and by the writer[3] at the 1914 session of the American Medical Association, and at that time aroused considerable adverse comment because it was opposed to the experience of most of the workers in the field at that time, and was not in accord with the teaching of Abderhalden.

Since that time, however, much work has been done on the typical Abderhalden test, and on a modification which tests for the antitryptic value of the serum in the various conditions, including pregnancy. In this country Jobling and Petersen[4] have led the work, and have shown that the antitryptic power of the blood serum is increased in some of the conditions in which I have demonstrated the increase of the tryptic power of the blood serum.

In collaboration with Eggstein,[4] they have produced evidence which, if substantiated, will destroy some of the underlying principles of the Abderhalden theory. They believe that the placental tissue has an affinity for, and absorbs the antitryptic substances present in the serum, and that the tryptic ferments are then free to digest the serum proteins. This view had been previously worked out by Adachi in Berlin,[5] and he has advocated the use of the Rosenthal modification of the Fuld-Gross method of antitrypsin determination instead of the Abderhalden test as a diagnostic aid in pregnancy. Among other men who have arrived at substantially the same conclusions, are Bronfenbrenner,[6] De Waele,[7] Kjaergaard,[8] Oller and Stephan,[9] Plaut[10] and others.

Concerning the present status of this question, the following conclusions seem justified:

1. The Abderhalden test is not a specific and infallible test for the diagnosis of pregnancy, carcinoma or any other condition.
2. A negative reaction in a given case is of great value as speaking against the possibility of pregnancy.
3. A positive reaction must be interpreted as only speaking for the diagnosis of pregnancy, and that only in the absence of a large number of pathologic conditions, to some of which I have already called attention.
4. The ferments are increased in the blood during pregnancy. As yet, however, no way has been devised of differentiating between these ferments and the ferments mobilized in many pathologic conditions.
5. The test should be done in all cases in which the diagnosis of pregnancy is in doubt, with a full knowledge of its limitations and possible error. It should be regarded as corroborative evidence together with other clinical phenomena.

These conclusions are in accord with what any one familiar with biologic reactions would expect. There is no known serum test or reaction at the present time that is absolutely reliable for diagnostic purposes. The Wassermann reaction cannot be relied on in all cases, and the same can be said of the various complement fixation and precipitin tests. Nobody doubts at the present day the value of the Widal reaction in typhoid fever, and yet no clinician would care to base a diagnosis of typhoid on that alone, and insist that he could not be wrong.

The subject should be approached from a broad point of view, and the Abderhalden test must be given its place along with other biologic reactions. Its value as a diagnostic measure must be decided by the slow accumulation of facts, by careful workers in scientific laboratories; and its right to endure must depend on their verdict.

Concerning the confusion that may arise regarding the work done on the antitryptic power of the blood serum in various conditions, I should like to point out that the antitryptic power of the blood is raised in the same conditions as the tryptic power. While for theoretical purposes it is very important to understand that the placenta is not digested by the ferments in the Abderhalden test, but merely adsorbs the antitrypsin, and leaves the trypsin free to digest the serum proteins, practically this method is a test of the tryptic activity of a given serum after the adsorption of the antiferments, which have been mobilized in all probability in response to the increased tryptic content of the blood.

2800 Washington Boulevard.

THE FEEDING OF BILE COLLECTED FROM BILIARY FISTULAS IN OBSTRUCTION OF THE COMMON DUCT

JOHN C. A. GERSTER, M.D.
Adjunct Attending Surgeon, Mount Sinai Hospital; Assistant Attending Surgeon, Knickerbocker Hospital
NEW YORK

In 1912, Schmilinsky[1] reported a case in which a biliary fistula developed after resection of the stomach for ulcer followed by gastro-enterostomy. From 800 to 1,000 c.c. of bile were discharged per day. The stools were acholic. The patient was losing strength so rapidly that it became apparent he could live but a few days longer. Schmilinsky met this crisis by collecting all the bile escaping from the fistula and introducing it into the stomach through a stomach tube twice a day (about 400 c.c. each time). The treatment was kept up for two months. The patient bore it excellently. As the fistula showed no tendency toward closing, an anastomosis was made between it and a loop of jejunum. A cure is reported to have followed.

This eminently simple means of improving the condition of such patients was carried out by me in the following case:

Nov. 25, 1914, Benjamin F., pedler, aged 44, was admitted to the Third Surgical Division of Mount Sinai Hospital. A year previously he had been forced to stay in bed a week by an attack of right hypochondriac pain accompanied by fever and jaundice. Two weeks previously another attack of pain in the right hypochondrium forced him to stay in bed. There was jaundice of one week's standing. During the past two days there had been repeated chills.

Physical examination showed a greatly prostrated, deeply jaundiced man with high fever, who gave the impression of being intensely septic. A right hypochondriac mass reached to the umbilicus.

Shortly after admission, the abdomen was opened through a Sprengel transverse incision, and a large pericholecystitic abscess was evacuated; the small, almost normal gallbladder, adherent to the duodenum, formed part of the lower wall of the abscess cavity. When it was opened, much purulent bile escaped; a severe cholangitis was present. The patient's miserable condition forbade prolonging the operation by exploration of the common and hepatic ducts; the abscess cavity and cystic duct were drained, and the abdominal wound closed up to the point of drainage.

A stormy long-drawn out convalescence ensued, complicated by cholemic oozing on the seventh day after operation (controlled by packings inserted under general anesthesia—the cut margins of the gallbladder mucosa were seen seeping blood), and further by a bronchitis with remittent temperature.

Finally seven weeks after operation (Jan. 14, 1915), the patient presented the following picture: There was no fever; the general condition was very poor; the pulse was of miserable quality; there was marked emaciation; all bile escaped through the fistula; the stools were white. Tentative closure (plugging) of the fistula caused cramps and failed to divert the flow of bile into the duodenum; evidently there was obstruction of the common duct. The patient's great weakness forbade operation. Following the procedure described by Schmilinsky for the management of such cases, all the bile was collected and introduced into the stomach by means of the stomach tube twice a day (8 ounces each time—16 ounces per day). At no time was there the slightest nausea. The collection was most conveniently carried out by a catheter which snugly fitted the fistula and led the bile into a bottle attached to the belt and worn under the clothing.

A remarkable improvement took place. The appetite became much better.

Accordingly, Jan. 29, 1915, the abdominal wound was reopened under local anesthesia (1 per cent. novocain-potassium sulphate); then, under nitrous oxid-oxygen anesthesia, through a supraduodenal opening in the common duct, a stone impacted in the papilla of Vater was extracted. The common duct was drained with a small soft tube and the abdominal wall closed by layer suture up to the drainage tube. There was no febrile reaction for the first two days. On the second day cardiac decompensation occurred which, however, yielded to suitable stimulation in combination with the semiupright posture. From now on convalescence was uneventful. The patient was discharged cured, February 19; the fistula had closed; the stools were brown. He was presented before the Surgical Section of the New York Academy of Medicine, March 5, 1915, having gained 10 pounds since leaving the hospital.

The experience of Kausch[2] shows that bile cannot be administered by the mouth. A mixture of bile and red wine was tried. At the end of a week the patient refused continuation of the treatment. During this week, the entire amount ingested totaled but 445 c.c., an insufficient quantity to be of value to the organism.

The advantages of bile feeding by stomach tube for temporarily improving matters sufficiently to permit of further surgical intervention have been indicated above. As a permanent method in cases of inflammatory destruction of the common duct in which the lumen of the duct proximal to the papilla cannot be reestablished, it seems more troublesome but far safer than the forms of anastomosis employed at present in joining the biliary and intestinal tracts. Only too often does one read of death from ascending infection a year or two after operation and after months of apparent health.

CONCLUSION

The administration of bile in physiologic quantities, as just described, is a method for materially improving the condition of debilitated patients with biliary fistulas and common duct obstruction which seems distinctly worth extended trial.

34 East Seventy-Fifth Street.

Nursing Mother's Diet.—Nearly every writer on subjects related to maternal nursing, has declared against the view that certain foods ingested by the mother are capable of producing disturbances in the infant through the breast milk. Sour foods, fruits and gas-producing vegetables may be eaten by the mother if they do not cause discomfort to her. They produce no changes in the composition of the breast milk.—Isaac Abt, *Detroit Med. Jour.*, February, 1915.

AN UNUSUAL CASE OF GENERALIZED NONPIGMENTED SARCOMAS OF THE SKIN

ALFRED SCHALEK, M.D.
AND
OSCAR T. SCHULTZ, M.D.
Professors of Dermatology and Syphilology, and Pathology and Bacteriology, Respectively, University of Nebraska, College of Medicine
OMAHA

Sarcoma of the skin appears in several clinical varieties: it may be single or multiple, pigmented, nonpigmented, melanotic or hemorrhagic. It may remain limited to the skin or attack the viscera, and may be either primary or secondary. General primary nonpigmented sarcomatosis of the skin, especially of such rapid and extensive development as in the present case, is sparingly mentioned in textbooks and in the literature, and is sufficiently rare to be of interest.

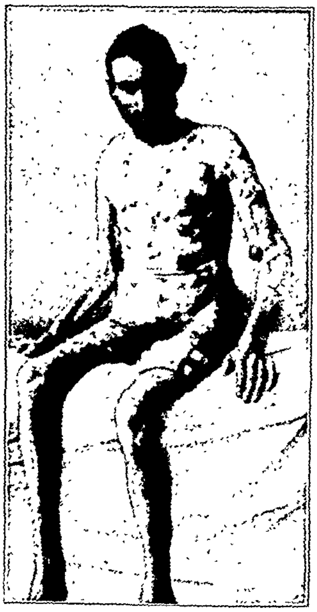

Fig. 1.—Patient with generalized nonpigmented sarcomas of the skin.

Considerable confusion exists as to its place as a clinical and pathologic entity. General sarcomatosis is sometimes used as an alternate name for granuloma fungoides, and is by many considered to be related to the latter or to leukemia cutis. Unquestionably there are some cases which form a connecting link between these diseases, but it is beyond discussion that in others no grounds can be found to put them in the same class. In the case here reported, the absence of a premycotic stage, of subjective symptoms and of any ulcerating tendency is sufficient to exclude mycosis fungoides. The glands and the blood having been practically normal, leukemia could not be considered. Kaposi's grouping of mycosis fungoides, lymphodermia perniciosa and true sarcomatosis, including the multiple pigmented variety, under the collective name of sarcoid tumors, is partly to blame for the present unsettled status of entirely different pathologic conditions.

The present case is interesting from several points of view. While the tumors were present both in the skin and internally, we think we are justified in considering the skin the primary seat for the reasons mentioned below. The first tumor appeared on the flexor surface of the left forearm in a warty lesion of long duration in an individual of perfect health. The largest tumors were found in the skin, which permits the theory that they had existed longest and had had more time to develop. If the internal tumors had been present for any considerable time before their appearance on the surface, earlier and more severe constitutional complications would have been observed.

Unusual features of this case were the absence of subjective complaints such as pain or itching; the skin above and around the tumors remained normal in appearance and color until the very last; not a single tumor underwent degeneration and ulceration. Death was caused by asphyxia due to compression of the trachea. The patient was in our care three weeks after the start of his illness until his end, and close observation of his symptoms, microscopic examinations of excised specimens during life and finally a necropsy permitted a thorough study of his condition.

P. N., white, Dane, laborer, aged 39, entered the hospital Dec. 1, 1914, referred by courtesy of Dr. C. F. Baumeister, Avoca, Iowa. His parents had lived to an old age. The patient had always been healthy up to the time of his present illness. There was no venereal history. Three weeks prior to his admission to the hospital he noticed a small subcutaneous nodule on the inside of the left forearm in the place of a pigmented papillomatous lesion which had existed for many years without appreciable change. From this time on new nodules appeared rapidly in different places, until they were present all over the surface, gradually covering most of the body. The lower extremities were least involved. Five hundred and sixty-three tumors were counted. At first they were subcutaneous, the size of a marble and movable. As they grew larger they became adherent to the skin above and to the fascia, muscles and periosteum below. The elevation above the skin became gradually more prominent, reaching the size of a filbert to an orange. The largest were located on the right side of the neck and the inner surface of the elbow of the left arm. Their consistency was hard, almost wooden, with no soft or fluctuating areas. There was no tendency to degeneration and ulceration. The skin above and around the tumors was smooth, normal in color, except in a few, where hyperemia and telangiectases had been produced by compression of the superficial capillaries. The contour of the growths was globular, with a few nodular irregularities. The patient did not complain about itching or pain. He had lost considerable weight since the beginning of his illness, and looked cachectic. He was in a slightly stuporous condition at the time of admittance, and very little information could be gained from him. Toward the last he had difficulties in breathing and swallowing and frequently vomited undigested food. Blood appeared in the feces early.

Blood: Hemoglobin 80 per cent. (Tallqvist). Red blood corpuscles, 5,170,000; the cells irregular in size and shape. White blood corpuscles, 7,180.

Urine: Amber, cloudy, with considerable sediment. Specific gravity, 1.030. No albumin, sugar, indican or blood present. Urates present.

Gastric Examination: Total acidity, 38; free hydrochloric, 4. Lactic acid and blood absent. Considerable mucus and many food particles.

The temperature was nearly normal to the last. The pulse was rapid and feeble.

The patient was considered hopeless from the start and a prognosis was made of a rapidly fatal ending, on account of the extreme involvement. Subcutaneous injections with Fowler solution, 5 drops daily, were tried without results.

On the eleventh day the patient had involuntary bowel movements. From the tenth day on he could not swallow any food and had to be fed by nutritive enemas, which were not retained. He died on the sixteenth day after admittance to the hospital, dyspnea and cyanosis having been extreme during the last days.

The chief pathologic interest relates to the distribution and the structure of the tumors. In the skin these were most numerous and most prominent on the arms, chest, abdomen, back and thighs. The largest mass, which measured 8 by 5 cm. and protruded 4 cm. above the level of the surrounding skin, was present at the inner surface of the left elbow, at a point a short distance from the wartlike growth which had been removed thirteen days before death. Over the right zygoma was a mass 5 cm. in diameter, and beneath the chin another of equal size. The remaining, innumerable nodules varied in size from this down to such nodules as were just visible. With the exception of the two large tumors mentioned, the skin of the face and neck was free. The skin over the largest and medium sized nodules appeared thinned and was intensely congested, with a diffuse, bluish-red color. Over the summits of the smaller nodules fine, dilated, radiating vessels could be seen. No nodules could be seen on the forearms and legs, but very many could be felt beneath the skin, and an occasional very small one could be palpated in the skin of the dorsal surface of the hands and feet. The skin felt firmly attached to the larger masses. The smaller ones were freely movable in the subcutaneous tissue. No nodules were present in the mucosa of the mouth. The superficial lymph nodes were just palpable and apparently were not involved. There was no subcutaneous or omental fat.

Within the body the distribution of the tumors was striking in that, while nodules were present in uncountable numbers, the internal organs themselves were almost entirely free. The heart muscle contained a few, the largest 1 cm. in diameter. Three were present beneath the capsule of the liver, the largest 7 mm. in diameter. Within the left suprarenal was a single mass 3 cm. One loop of the middle third of the ileum, which lay superficially in lower half of abdominal cavity, contained several nodules, the smallest 5 mm., the largest, which was flattened, mushroom shaped, pedunculated and protruding into the lumen, 1.5 cm. in diameter. With the exceptions noted, the internal organs were free of macroscopic tumors, and no tumor tissue was found on microscopic examination.

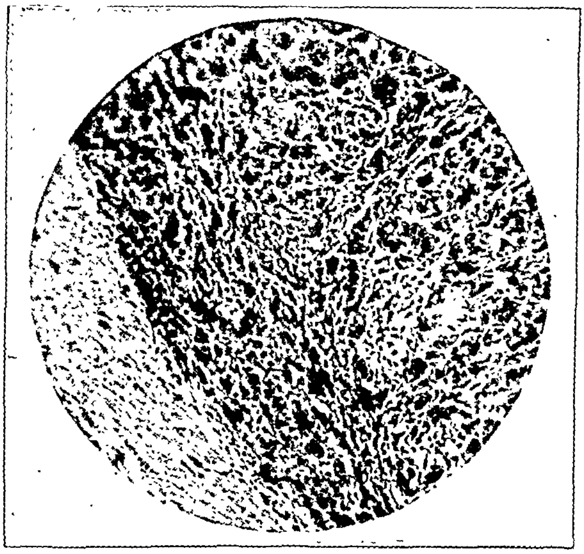

Fig. 2.—Myocardial metastasis. Small alveoli with a minimal amount of intervening stroma. The margin is sharply defined, unencapsulated, and there is no invasion; × 120.

The large number of nodules present within the body were scattered about in the mediastinal, the omental, the mesenteric and the retroperitoneal tissues. Behind the upper end of the sternum was a large multilobulated mass which completely filled in the space behind the manubrium. The posterior mediastinum contained numerous masses, most marked at the hilum of the lung, but not involving the bronchial lymph nodes. In the omentum, the tumors, too numerous to count, varied in size from shotlike nodules to an ovoid mass 5 by 5 by 3.5 cm. Most of the omental tumors were sessile, attached by very fine, long, fibrous peduncles. In the mesentery nodules were also numerous, being largest at the root of the mesentery. Large numbers of tumors were present in the retroperitoneal tissue, the largest ones being present about the kidneys and suprarenals. The pelvic tissues and organs were free.

The site of predilection for the tumors, both in the skin and in the internal tissues, was the loose areolar tissue. The nodules were sharply defined, pale, succulent, translucent, almost fatlike on section. The congestion noted over the large skin tumors was limited to the overlying skin.

Microscopically the alveolar arrangement of the tumor tissue is so pronounced as to suggest carcinoma. The alveoli are round, oval or elongated in shape, and vary considerably in size. In some of the tumors rather broad bands of dense fibrous stroma separate the alveoli; in others only very narrow stroma bands are present. Peripherally the tumor tissue is sharply defined, often surrounded by a thin layer of fibrous tissue. Only in the suprarenal metastasis and in one of the myocardial nodules is there any evidence of invasion at the periphery of the tumor tissue. Growth appears to have been almost wholly expansive.

The tumor cells vary in size and shape. The smallest, which are rounded or oval, average 18 microns in diameter. Somewhat larger cells are polyhedral, and the largest, which may measure 85 microns and more in diameter, are very irregular in outline. The nuclei are round or oval, vesicular, rich in fluid, with finely granular chromatin distributed in the form of a closely meshed network. Some nuclei are hyperchromatic. Most of the nuclei have distinct nucleoli, which stain deeply with hematoxylin. The larger cells are multinucleated; in many the nuclei are multilobulated. The cytoplasm is homogeneous, dense, very finely granular, and stains rather deeply with eosin. The cytoplasm of some of the cells contains light brown pigment so finely granular as to give the protoplasm a diffuse coloration. Mitotic figures are extremely rare. Evidences of direct division, on the other hand, abound, the great majority of the cells having nuclei in stages of direct binary fission or single or multiple budding.

The most striking lesion, histologically, is the tumor removed thirteen days before death from the ulnar surface of the left forearm, just below the elbow. This, which originally had a wartlike appearance, had been present for many years. As has been noted, it had begun to grow three weeks before admission to the hospital. Half of it became transformed into a smooth, rounded mass, identical in external appearance with the multiple tumors which developed so rapidly later. At the time of removal, the entire mass was 3 cm. in diameter and 0.8 cm. thick. It was sessile, attached by a short pedicle 3 mm. in diameter. One half had the rough, papillomatous surface of an ordinary wart; the remainder was round and smooth. Sections through the entire tumor show clearly the coarsely papillomatous character of the original tumor. The smooth portion is identical with the tumor nodules present in the skin and in the deeper areolar tissues. In the papillomatous portion are seen all gradations from the structure of a typical lymphangioma hypertrophicum to that of the metastasizing endothelial tumor tissue. The gradations are not seen in a single papillary outgrowth. The smaller ones contain numerous elongated and bandlike or round nests of closely placed, small, irregularly cuboidal cells. A large amount of granular, dark brown pigment is present beneath the epidermis; some occurs in cells between the lymphangiomatous islands, but the cells of the latter are free of pigment. An occasional thin epidermal downgrowth extends for some distance into the underlying stroma. In a medium sized papillary outgrowth the cellular alveoli are very closely placed and the individual cells are somewhat larger. In a still larger outgrowth occur numerous alveoli identical in appearance with the nodules elsewhere. In this and in the smooth, nodular half of the primary tumor the epidermis is compressed and thin, its under surface smooth.

For the peculiar distribution of the tumors it appears difficult to offer a satisfactory explanation. The parenchyma of the internal organs remained almost wholly free of metastases. The superficial lymph nodes, as well as the bronchial, mesenteric and retroperitoneal nodes, were in general spared. In the clinical and postmortem examination there was no evidence of obstruction to vascular or lymphatic channels, and similar evidence is wanting in the microscopic examination of the tissue about the tumor nodules, although particular attention was paid to this point as offering a possible explanation of the peculiar distribution of the tumor nodules in the skin. In view of the large number of tumors and of their widespread distribution in the deeper tissues as well as in the skin, it appears necessary to suppose a generalized distribution of tumor cells by way of the circulation. But why the development of tumors from such cells was confined almost entirely to the loose areolar tissues is a point in explanation of which we can only suggest variations in tissue susceptibility or resistance.

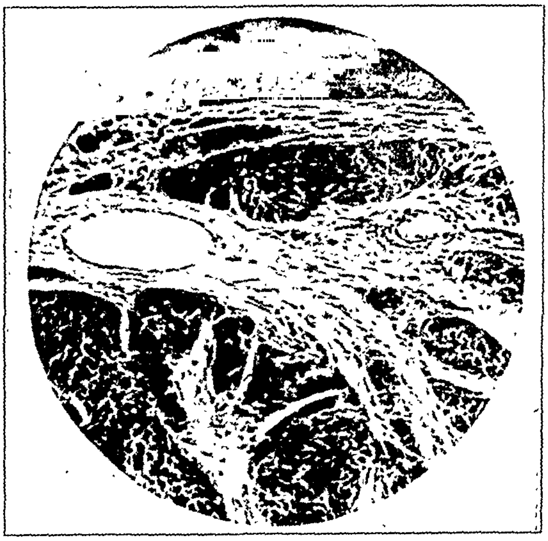

Fig. 3.—The primary tumor. Large alveoli in the subepidermal stroma; × 120.

SUMMARY

Sarcomatosis cutis includes several conditions, the inclusion of some of which among the true blastomas does not appear entirely justifiable. This is true of the idiopathic multiple pigment sarcoma of Kaposi, the presence of true [illegible] cells in this condition also being nc [illegible] absolute certainty. The diffuse sarcomatosis of Kaposi is apparently the same as mycosis fungoides, which, in its earlier stages at least, has the histologic characters of an inflammatory granuloma rather than that of a true tumor. Multiple true sarcomas of the skin may arise from a primary skin tumor or they may be metastases from tumors of the internal organs; structurally they may be round or spindle cell, or they may be composed of pigment cells.

In the case reported, the sarcoma type, if one chooses to classify the tumor among the sarcomas, is the lymphendothelioma.

Over five hundred visible skin nodules were counted. There were in addition very many palpable but invisible tumors.

Innumerable nodules were present in the mediastinal, omental, mesenteric and retroperitoneal tissues. The parenchyma of the internal organs and the lymph nodes remained practically free of tumors.

The primary tumor developed from a papillomatous lesion near the elbow. Histologically this lesion was a lymphangioma hypertrophicum.

The case was characterized by the very rapid development of the secondary tumors. The first change in the previously benign primary lesion was noticed three weeks before admission to the hospital; death occurred on the sixteenth day after admission.

TUMOR OF THE THIRD VENTRICLE

LEWIS J. POLLOCK, M.D.
CHICAGO

In a careful summary of the literature, T. H. Weisenburg[1] collected thirty cases of tumor of the third ventricle, and, by a review of the clinical and pathologic findings, established a syndrome. He distinguishes three symptomatic groups:

1. Those cases in which a tumor of a moderate size is situated in the floor of the third ventricle, and in which there is no extension into the foramen of Monro or aqueduct of Sylvius.
2. Small tumors so situated as to obstruct the foramen of Monro and whose position can be changed by deviation of the head.
3. Those tumors, whether large or small, which either extend into the aqueduct of Sylvius, affecting the surrounding structures by direct extension or pressure, or those in which the posterior portions of the cerebral peduncles and pons are compressed, either by direct pressure or by dilatation of the aqueduct of Sylvius.

The first class does not offer specific symptoms, but presents evidences of internal hydrocephalus, namely, headache, choked disk, nausea, vomiting and dizziness. In tumors of large size, indirect pressure on the internal capsule causes paresis of the corresponding limbs. These symptoms may likewise result from internal hydrocephalus alone. The reflexes are nearly always increased. The mental symptoms, generally supposed to be present in tumors of the third ventricle, are attributed by Mott[2] to the impairment of the function of the cortex as the result of the pressure of the dilated ventricles.

The second class is unimportant as but one case has been observed. This group presents a variation in symptoms of headache, nausea and impairment of vision on tilting the head forward.

---

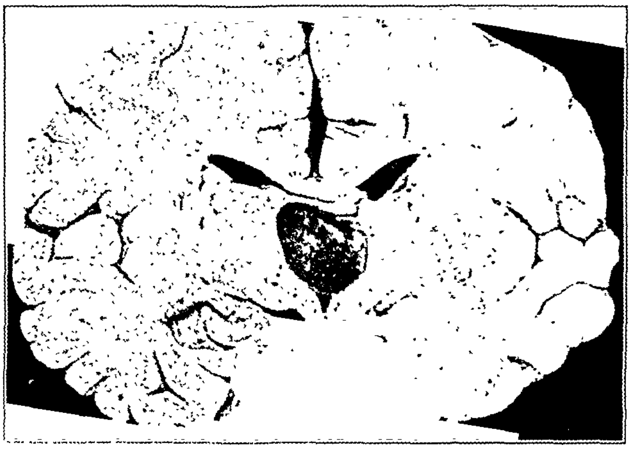
1. Weisenburg, T. H.: Tumors of the Third Ventricle, with the Establishment of a Symptom Complex, Brain, 1910, xxxiii, 236.
2. Mott, F. W., Wakelin Barratt, J. O.: Arch. Neurol., 1900, i, 417.

The third class offers a fairly well recognizable syndrome. The symptoms arise from involvement of the third nuclei, red nucleus, or superior cerebellar peduncles and from pressure on, or destruction of, the posterior longitudinal bundle or the intercommunicating fibers between the third nuclei. Among the symptoms noted are disturbance of associated ocular movements, oculomotor palsies, large pupils with impaired reaction, protrusion of the eyeballs, cerebellar ataxia, symptoms arising from pressure on the pineal gland and the general symptoms of tumor cerebri.

The following case did not present sufficient symptoms to permit localization of the tumor during life, but it possesses an interesting feature relative to the classification of tumors of the third ventricle.

History.—E. O., woman, aged 48, single, dressmaker, with a common school education, was admitted to the Kankakee State Hospital, March 21, 1911. The family history was negative as to points having any bearing on the disease. Nothing was obtainable concerning the patient's childhood. She was ordinarily of rugged health. She was not addicted to the use of alcohol. Nothing was known of any previous illness.

The present illness dated back to July, 1910, when it was noticed that the patient's memory was becoming defective. She became stuporous, apathetic and somnolent and became careless of her appearance, untidy and filthy Further than the fact that she had lost 20 pounds in weight, there was no reliable statement as to her physical symptoms From the patient it was ascertained that she had had dizziness and headache.



Tumor of third ventricle.

Examination.—At the time of admission this revealed a well-nourished woman whose height was 163.75 cm. (5 feet 4½ inches), weight, 91.8 kg. (202 pounds), with no deformities or malformations The skin showed slight icteric tinge. There was no skin eruption. Examination of the lungs showed nothing abnormal. The heart was not enlarged, sounds were normal, pulse was regular, 100 per minute sitting, 108 standing, tension high. Abdominal wall and contents were negative. Organs of generation were negative. Urinalysis showed trace of albumin, pus and blood cells, no sugar.

Neurologic Examination.—Station and gait: The patient stands with lordosis. Sways slightly in the Romberg position. Cannot walk a straight line, gait is shuffling, toes point outward, has difficulty in turning quickly. In walking she bends backward, taking short steps which increase in rapidity, causing the patient to collide with any object obstructing her path.

Active Movements: Right side of the body slightly larger than the left. Left dynamometer 50, right 72. There is no inequality in movements of the muscles of the face. She wrinkles forehead, closes eyes, shows teeth, whistles and opens and closes mouth equally well on both sides. Ocular muscles show no paresis. There is no nystagmus, no exophthalmos. Tongue apparently deviates somewhat to the right when protruded, probably on account of an asymmetry, of the teeth. Articulation is defective, slurring and lisping being present. Active movements of all four extremities are possible and well carried out with good power.

Passive movements show general increase of resistance. Tremors: Slight tremor of fingers, not intentional and more marked on the right side. Tendon and Joint Sense: At times the patient mistakes direction of movements of great toe; otherwise she does not show any change. Approximates finger to finger and finger to nose accurately. There is perhaps a slight clumsiness of movements of the left hand. Sensation: Tests for pain and touch sensibility not well responded to, owing to lack of cooperation. Patient does not take much notice of light touches on the left leg and toes, less on the right. Can feel slightest touch on the face. Makes numerous mistakes as to heat and cold on both sides. Stereognostic sense shows no defect.

Reflexes: Corneal and palatal present. Pupils 2 mm. in diameter, equal, react to light directly and consensually and also in convergence. Epigastric and abdominal present on left, absent on the right side. Plantar reflexes both of flexor type; at times extension of great toes occurs, but it appears to be a voluntary movement. Gordon absent. Has soiled herself several times. No incontinence of urine. Masseters, triceps and wrist jerks equal and normal. Knee jerks increased. Bilateral ankle clonus.

Special Senses: Olfactory normal. Visual fields apparently full. Hypermetropia. Hearing normal. Taste: Sugar is sweet on right, no taste on left; salt is sour on right, bitter on left. Does not recognize vinegar on right, calls it bitter on left. Owing to the mental state of the patient, replies cannot be relied on.

On lumbar puncture the cerebrospinal fluid gushed out, afterward dropped 60 drops per minute. Noguchi and Nonne-Apelt tests negative. Fehling test strongly positive, 2 cells per cubic millimeter.

Mental Examination: The patient is quiet and entirely passive, saying and doing nothing spontaneously. She presents an appearance of fatuous contentment, frequently smiles inanely and takes no interest in her surroundings. She shows no distress concerning the involuntary bowel movements. She is entirely disoriented and does not grasp the meaning of the situation even when it is explained to her that she is in a hospital for the insane. She, however, seems to realize that she is not clear by saying that "things seemed confused," but does not react in any way suggestive of perplexity. Cooperation is poor and she often does not answer questions, apparently from lack of interest. Memory, as far as can be tested, is extremely defective, and she seems unable to retain any facts given as tests of impressibility. The general fund of information also seems to be very deficient. No sense falsifications or delusional trend can be discovered.

The main features are therefore those of extreme mental dilapidation, without any localizing signs on the part of the projection system.

June 2, 1911, difficulty in standing increased. Gait now resembled a continuous falling forward, with an attempt to regain equilibrium. Patient complained of headache occasionally. Memory defect increasing.

July 1, 1911, patient was unable to stand or sit up, and during this week became rapidly weaker. Greatest weakness appeared to be in the lower extremities. In replying to questions, the patient's answers were irrelevant. No abnormalities were noted in the ocular muscles, although frequently looked for.

July 13, 1911, death occurred.

Postmortem examination was limited to the brain. On section there was found a tumor of the third ventricle.

Macroscopically the tumor consists of an encysted colloid growth, situated in the third ventricle and probably originating from the ependyma. It is attached to the inferior surface of the center of the fornix and velum interpositum. It is ovoid in shape, thickest at the center, where it is about 2 cm. in diameter, and rapidly decreasing in size anteriorly and posteriorly to small pealike extremities. The growth originates posteriorly to the anterior commissure, occluding the foramen of Monro on the right side and dilating it also. By virtue of the direction of its growth from left anterior to right posterior, the tumor enters the lateral ventricle of the left side through the foramen of Monro (which it occludes). The ventricular portion of growth is about the size of a pea, greenish, mottled with yellow. The tumor by the growth drags the septum lucidum and fornix to the right and compresses the right optic thalamus more than the left. Below it lies on and separates the corpora albicantia and rests on the infundibulum. The anterior extremity of the growth, which projects into the lateral ventricle, passes above the anterior commissure. The tumor extends backward to a point just anterior to the middle commissure, where it ends in a small pealike growth. A plica in the septum lucidum curved to the right persists throughout. The tumor does not press on the red nucleus or occlude the entrance to the third ventricle posteriorly to the middle commissure.

The pineal gland is not encroached on. The aqueduct is small and the third ventricle above the middle commissure is dilated. The tumor is dark green except at the anterior portion, where it is mixed with yellow. The capsule surrounds it entirely and it is easily shelled out except at the upper and lateral right borders where it tears, showing a colloid, cheesy appearance, spotted with what appears to be degenerated blood pigment. The capsule is attached on both sides to the walls of the lateral ventricles, and the choroid plexus is seen to enter the third ventricle beneath the capsule of the tumor and forms a very slight elevation. The lateral ventricles are dilated, the right more than the left, and the choroid plexus on both sides show the formation of small cysts.

Microscopically the tumor consists of an encapsulated colloid cyst originating from a glioma. At the portion firmly attached to the cyst wall, the greatest number of undegenerated cells and nuclei are found. The capsule at this point is thickened, the connective tissue forming layers, between which are seen numerous lymphocytes, glia nuclei and a few Abraumzellen. The optic thalamus beneath this portion of the capsule is seen to contain a few Abraumzellen and a greater number of neuclei. The tumor proper consists of a greenish homogeneous material, embedded in which are numerous Abraumzellen, staining red with scarlet r. containing many globules, showing black with Bielchowsky stain. Within the Abraumzellen are found nuclei showing fatty degeneration, red blood cells and débris, fatty granules, and at the periphery of the cells, frequently a crescentic flattened nucleus. There are likewise seen throughout the tumor many colloid bodies, nuclei, lymphocytes and red blood cells. There are no fibers found within the tumor mass.

It is interesting to note that of thirty cases of third ventricle tumor collected by Weisenburg, only three extended into the lateral ventricles at all, and these protruded only slightly through the foramen of Monro, as was the case with the tumor here recorded. The tendency for growth is in the direction of the flow of cerebrospinal fluid. It is apparent that this tumor, which occluded the foramen of Monro, whose position did not change with deviation of the head, which did not extend into the aqueduct of Sylvius, and which but slightly compressed the pons, would, according to Weisenburg's classification, be placed in the third group. It would seem possible that, had not this tumor attained such a large size, it would have occupied the same position without resulting pressure on the pons, and, in such case, should properly be placed in a separate group in which the tumor is so situated that it occludes the foramen of Monro whether its position changes with variation in the position of the head or not. The cases in which these tumors are changeable in position should then be classified in a subgroup under this head. The symptoms of the group would be dependent on, first, the degree of hydrocephalus and, second, the amount of pressure on the surrounding structures. Inasmuch as there have been four colloid growths reported which did not extend into the aqueduct of Sylvius, and three other cases, excluding this tumor, which extended into the lateral ventricles through the foramen of Monro instead of the aqueduct of Sylvius, it is highly probable that this group will assume greater importance with the subsequent report of cases.

25 East Washington Street.

THE LESION IN A CASE OF SEROUS COLITIS

ROLFE FLOYD, M.D.
NEW YORK

Between the purely functional diarrheas, on the one hand, in which we believe no anatomic changes are associated with the disturbed activities of the bowel, and the well-defined dysenteries, such as croupous and amebic colitis, on the other, in which evident and often extensive lesions are always present, there lies a large intermediate group of cases, in which it is by no means easy to be sure whether actual anatomic lesions exist or not. The main reasons for our ignorance in this matter are first: such conditions are not, of themselves, fatal in adults so that postmortem examinations are rare; and second, if the changes are only those of congestion and exudation, they may easily be impossible of demonstration after death.

To the group in question, the general term "catarrhal colitis" is applied, and it may be subdivided as follows:

1. Catarrhal colitis in children which may become so severe as to take life, and regularly shows a swelling and sometimes a rupture of the solitary lymph follicles.
2. Catarrhal colitis in adults, with mucus the chief inflammatory product.

The lesion in these cases has been described by Delafield.[1] The lower end of the large bowel is the most frequently inflamed. The pathologic changes are congestion of the vessels of the submucosa and mucosa, with an abnormal quantity of mucus in the cells lining the tubules. There may be some emigration of leukocytes and some diapedesis of red cells. No ulcers occur, and the solitary lymph follicles remain unchanged. There are very frequent small passages composed of a few drams of mucus, in acute cases often blood streaked. Fecal matter is absent at first, and when it appears is usually formed, though very variable in amount. Colic and tenesmus accompany the movements. There is usually some fever.

As an example of this type I find the following among my records:

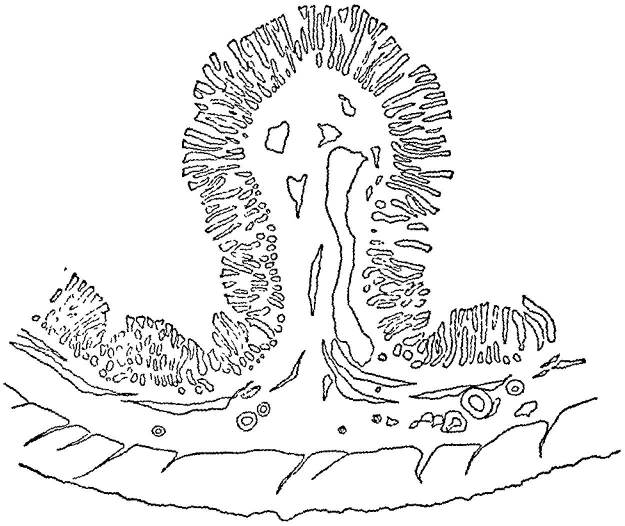
Case 1.—Man, aged 25, began at 3 a. m. to have repeated small movements of bloody mucus associated with colic and rectal tenesmus. A passage which I saw was composed of about 3 drams of bright bloody mucus and nothing else. The patient had little prostration and no fever and got well in two days with rectal irrigations.

---

[1] Delafield: Am. Jour. Med. Sc., N. S., 1897, cxiv, 401.

3. Catarrhal colitis in adults with serous fluid the chief inflammatory product.

This condition differs clinically from the foregoing. The passages are copious, from one-fourth to one pint, at first soft fecal, then simply gushes of watery fluid, either green or brown, often preceded by colic but unassociated with tenesmus. Blood does not occur, and mucus is absent or nearly so. The patients are prostrated and may even faint after a large passage. There is little or no fever. The condition lasts longer than the mucoid form, and if untreated, may run for weeks.



Camera lucida sketch of section of colon, showing outlines of the larger lymph channels in submucosa; × 15.

The following case, also from my private records, serves to illustrate the condition.

Case 2.—Man, aged 35, without known cause, was taken with abdominal cramps and chilly sensations followed by fourteen large watery movements in twenty-four hours. The passages contained a few flakes of fecal matter but no mucus or blood. He did not suffer with tenesmus. He vomited once, was nauseated and much prostrated. With rest in bed and appropriate drugs the symptoms promptly subsided.

The lesion of this form of colitis has, I believe, not been described. I wish, therefore, to report the following case from the second medical division of Bellevue Hospital:

Case 3.—A laborer, aged 41, was sick and died of a lobar pneumonia on the eighth day. On the sixth day of his illness, following a dose of salts, he began to have frequent copious watery discharges, without pain or tenesmus, which continued to the time of his death. In the two days he had about twenty passages of brown or green fluid, containing no fecal matter, no blood, and practically no mucus. He did not vomit. At necropsy, three hours after death, the heart was found normal. *The whole right lung was consolidated.* The stomach was distended with gas and a quart of light green, turbid, serous fluid, and its wall was coated with thick, tenacious mucus but not at all congested. The small intestine contained a moderate amount of viscid yellow chyle throughout. There was moderate gaseous distention of the jejunum; it was normal. The colon contained a little gas and was nowhere tightly contracted, though rather smaller than usually seen at necropsy. It was empty through its entire length, containing altogether about a half ounce of soft mucoid fecal matter, mostly in the caput. The mucosa was strikingly clean and edematous, looking as if it had just been washed in running water. There were no congestion, no ulcers, no hypertrophied lymph follicles. Under the microscope the mucosa and muscle coat were normal. The submucosa, only, was markedly thickened by edema, and its lymph spaces truly enormous. The accompanying illustration shows the relative dimensions of the larger ones. There were no congestion, no diapedesis of red or white cells and no follicular hypertrophy. There was marked thickening of the walls of the larger vessels, not due to muscular or connective tissue hypertrophy, but to a homogeneous swelling of their elements.

It is, of course, uncertain, with the bowel symptoms only an incident in the course of a lobar pneumonia and beginning after a saline, whether the lesion is characteristic of serous colitis or not. But necropsies are so rare and the pathologic features of the colon so definite and peculiar and yet so intelligibly associated with a copious serous exudate, that I have thought it proper to put the case on record as a contribution to the pathology of the condition.

A FENCE STAPLE IN THE LUNG

A NEW METHOD OF BRONCHOSCOPIC REMOVAL

Chevalier Jackson, M.D., Pittsburgh

The mechanical problem of the bronchoscopic extraction of an open safety-pin lodged point upward in the trachea or the bronchi is readily solved because of the ease with which the pin can be closed or cut in two for removal. With the double-pointed staple, however, we have to deal with a rigid body of tough steel that cannot be bent, sprung or broken. The author has succeeded in three cases in turning and withdrawing the staple by a method which is best illustrated by the last and most difficult case.[1]

Mr. W., aged 44, was referred to me by Dr. L. P. Warren of Wichita for the removal of a fence-wire staple which had been in the right lung for fifteen days, having been aspirated while being held in the mouth. There were no symptoms after the accident. Roentgenograms made for me by Dr. George W. Grier showed the staple to be in the lower lobe of the right lung (Figs. 1 and 2). Overlaying with my positive films of the tracheobronchial tree showed the

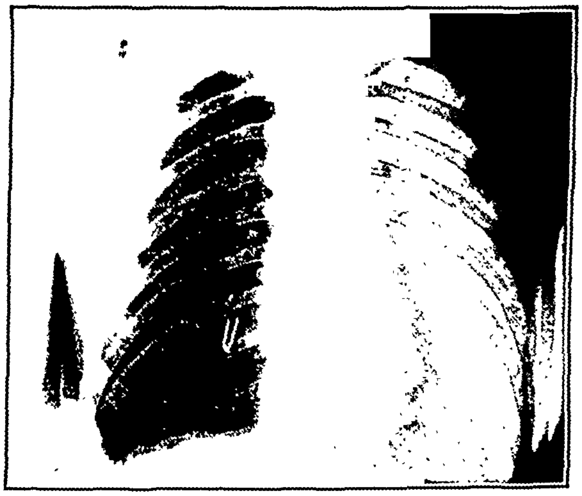


Fig. 1.—Anteroposterior view of chest showing staple in a posterior branch of the inferior-lobe bronchus. (From roentgenogram by Dr. George W. Grier.)

---

[1] Since the foregoing was written, a fourth case has been similarly successfully dealt with. The points of a very large staple were turned down into the opposite main bronchus.

staple to be in a posterior branch of the inferior lobe bronchus, the bottom of the staple being 4 inches (10 cm.) below the bifurcation of the trachea. Evidently, as is usual with foreign bodies pointed at one end, blunt and heavy at the other, it had worked down by a ratchet-like movement as far as it could go. Respiratory, pulsatory and bechic movements favored deeper lodgment but were powerless to force the intruder back because of the immediate catching of one or both points.

The bronchoscope was passed under local anesthesia. The staple was found tightly wedged in the smallest bronchus it could enter, evidently having reached this location by the ratchet-like action usual with such foreign bodies. Both points were concealed in swollen mucosa as shown schematically at *A*, Figure 3. Obviously, to pull on such a body would mean the ripping of the bronchial wall and certain death to the patient, even if it were possible to make sufficient traction thus violently to pull out the staple.

Working the body slightly downward with a forked rod passed through the bronchoscope, the points were liberated. The staple was slightly rotated with forceps so as to bring the points in new places. With the combined use of hooks, side-curved forceps and the lip of the bronchoscope the staple was gradually, after many slippings-back, manipulated about 1 cm. upward to a place where a pair of suitably spaced orifices of branch bronchi (*B*, *C*, Fig. 2) were available for the admission of the points. The curved end of the staple, *E*, was seized with my rotation forceps which form an eye on closing. Counterpressure being made with the bronchoscopic lip on the two points, the latter were guided into the branch orifices as traction with the forceps in the direction shown by the dart *F* caused the staple to turn over, loop-end upward. The staple being much too large to enter the bronchoscope, the loop was held against the bronchoscopic tube-mouth, the points trailing harmlessly behind, while the bronchoscope, forceps and staple were all withdrawn together, as shown at *K*. The duration of the entire procedure was one hour and twenty-one minutes, almost all of this time being consumed in the manipulation of the staple the one centimeter upward to the pair of branch-bronchial orifices. The anesthetic being local (cocain, 20 per cent.) the patient held his breath at command for a large part of a minute at many different times. Care was taken not to exceed the normally great resiliency of the tracheobronchial tree.

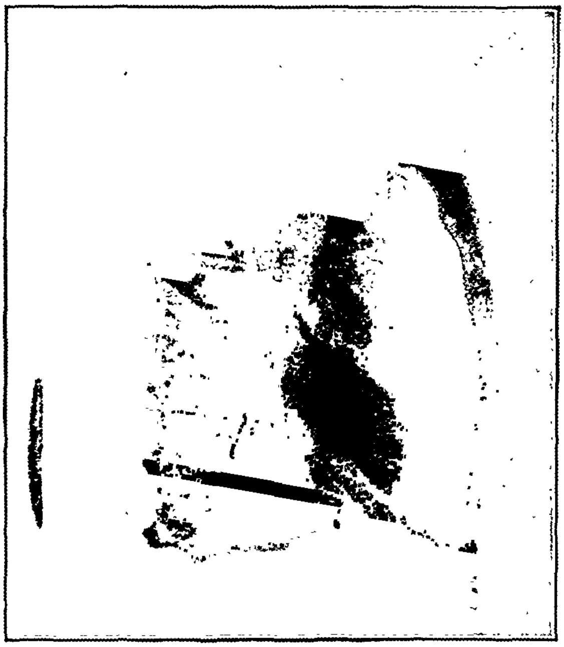

Fig. 2.—Lateral view of chest showing location of staple in lung. (From roentgenogram by Dr. George W. Grier.)

The patient had no rise of either temperature or pulse rate and left for his home in the west on the third day.

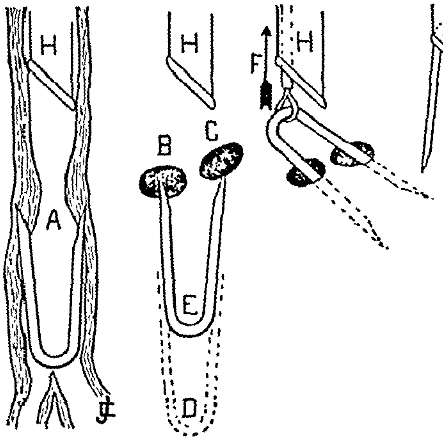

Fig. 3.—Schema illustrating a new method of removal (by version) of bronchially-lodged staples or double-pointed tacks. *H*, bronchoscope; *A*, swollen mucosa covering points of staple; *E*, the staple has been manipulated upward (*D* to *E*) with bronchoscopic lip and hooks until the points are opposite the branch bronchial orifices, *B*, *C*. Traction in the direction of the dart *F*, by means of the rotation forceps, counterpressure being made on the points of the staple, the points enter the branch bronchi and permit the staple to be turned over and removed with points trailing harmlessly behind (*K*).

Fig. 4. — Showing actual size of staple removed from the right lung, bloodlessly through the mouth, by bronchoscopy, after version as shown in Figure 2.

He is now, after three months, perfectly well in every way. The staple is shown, actual size, in Figure 4.

Ninth Street and Penn Avenue.

GAUCHER SPLENOMEGALY DIAGNOSED BY SPLEEN PUNCTURE BEFORE OPERATION *

E. P. Bernstein, M.D., New York

The following report should be of interest as it is the first case of its kind in the literature:

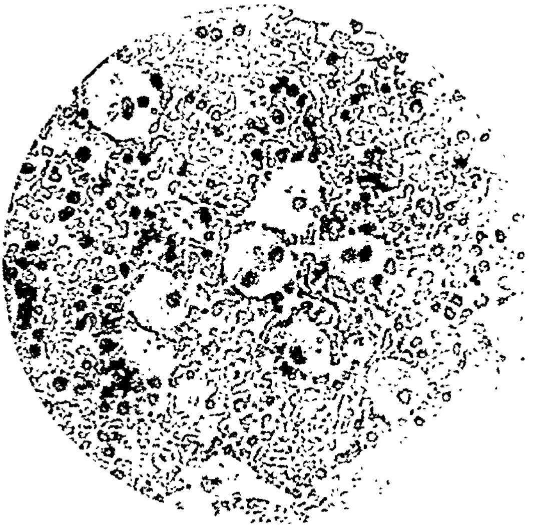

Fig. 1.—Smear from aspirated fluid. Giemsa stain. Low power, showing large multinucleated endothelioid cells.

The patient is the sister of a boy who had been successfully splenectomized by Dr. Henry Roth about two years previously for what was clinically diagnosed as Gaucher's disease and proved so after operation by histologic study of the spleen.

---

* From the Pathological Laboratory of the Lebanon Hospital.

Other than this family history and a moderately enlarged spleen, there were no symptoms pointing to or warranting the diagnosis of Gaucher's splenomegaly in the sister. However, she was referred from the Lebanon Hospital dispensary by Dr. Charles Herrman to the surgical service of the hospital under the care of Dr. Parker Syms for operation.

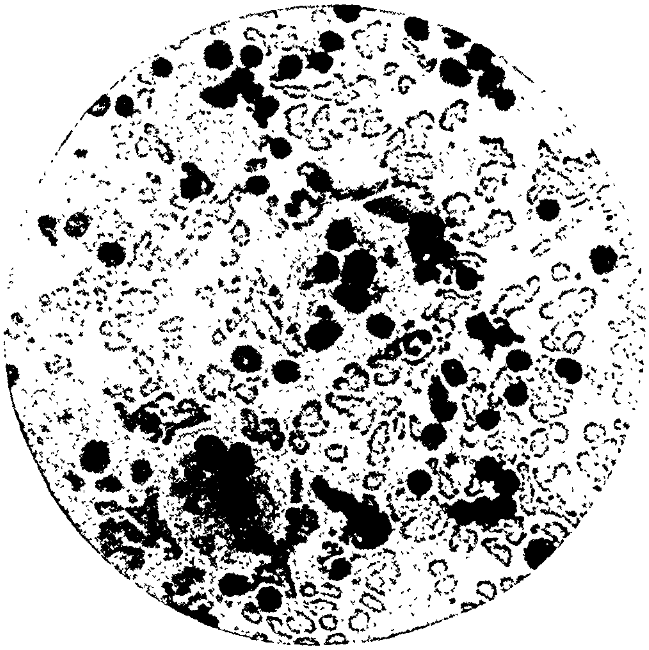

Fig. 2.—High power of Figure 1.

Dr. Syms was kind enough to follow my suggestion of spleen puncture before operation to establish the diagnosis. While the idea has been voiced before, it has never been tried. A simple puncture with a good sized needle and syringe was made and sufficient spleen pulp and blood mixture was aspirated to render a good sized drop in the needle. This was spread over cover glasses, fixed with methyl alcohol and stained with the Giemsa solution. The characteristic multinucleated endothelioid cells were found in abundance and the diagnosis established (Figs. 1 and 2).

The spleen on removal showed the typical pathologic picture of Gaucher's disease both in spreads of the spleen pulp and sections of the organ.

Aspiration therefore has been proved of final diagnostic importance and should be especially valuable in doubtful cases.

A Suggestion for Removing Foreign Bodies from the External Auditory Canal.—Louis S., aged 7 years, in some manner lost the segment of rubber from the end of a pencil in his left ear. With reflected light I found the rubber filling the diameter of the ear canal and close to the drum. Mere touching of the foreign body produced severe pain, and I decided on instrumental removal under anesthesia. With the ordinary ear instruments it was impossible to get behind the obstruction, and while in this predicament it occurred to me that the dentist has a suitable instrument for this emergency. I procured from my dentist a Donaldson spring-tempered pulp canal cleanser. This is a steel wire with spirally arranged barbs. This wire was easily twisted into the mass of rubber, and the firm grip of the barbs enabled me to remove the foreign body with ease. This dental instrument sells for 15 cents, and, placed in a lead-pencil holder, would be a useful instrument for similar emergencies.—F. P. Anzinger, M.D., Springfield, Ohio.

New Instruments and Suggestions

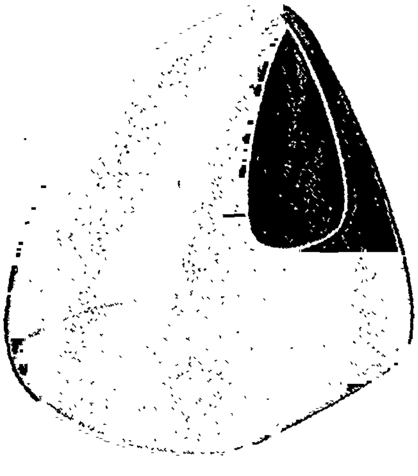
A SIMPLE MEANS OF OBTAINING SPECIMENS OF URINE FROM INFANTS

C. R. Spicer, M.D., Chicago

Routine urine analyses in an infant ward of a hospital disclose the fact that a substantial percentage of these little patients suffer from various kinds of urinary disturbances. Pyelitis and cystitis are common, nephritis by no means rare, as shown at necropsy, while acidosis and other metabolic disturbances are so directly reflected in the urine that, in the light of modern pediatrics, urine analyses are as important in infants as in older patients. The difficulty and inconvenience in procuring specimens of urine from babies, however, has doubtless caused much neglect in these cases.

A method commonly used is to strap a test tube or glove finger over the urinary outlet by means of adhesive plaster. This is usually effective, but it is considerable trouble to apply, even in boys, while in girls it is extremely difficult. Repeated applications of adhesive are also apt to cause excoriations of the skin. Some prefer to place the child on a bedpan. This is often successful, though troublesome, and defecation may also occur and contaminate the specimen. Straps of rubber are made to encircle the body or thighs and hold a test tube in position. While generally effective, they are uncomfortable to the child and troublesome to apply. Sponges and absorbent cotton are used, but with even less satisfaction than the foregoing schemes. The device here illustrated was made to meet the objections to the above methods.

The urinal has two plane surfaces, one on which it rests when not in use; the other, somewhat like a plane vertical section of a cone, is applied to the patient when procuring the specimen. An opening of suitable size and shape is located at the upper portion of this face so as to admit the penis or cover the vulva and admit the urine and exclude the feces. The other aspect of the device is convex, and when in use is covered by the diaper which holds it in place, no other means being required. It is molded in glass of sufficient thickness to withstand any ordinary stress. The capacity is about 15 c.c.



Infant specimen urinal.

The patient may be allowed entire freedom of movement. Owing to the shape of the flask and the location of the opening, it matters not whether he lies on his back, his side or his face, or whether he sits or stands; if urine is voided it will be collected and retained. When the diaper is loosened the urinal remains right side up.

While it was not originally intended to obtain twenty-four-hour specimens, by occasionally emptying the flask, quantitative amounts have been secured. The principal need in infants is a means of procuring a specimen of sufficient quantity for chemical and microscopic examination, free from contamination and without discomfort to the patient or trouble to the nurse. This simple device meets these requirements. It has been in use in the Children's Memorial Hospital for several months.

Children's Memorial Hospital.

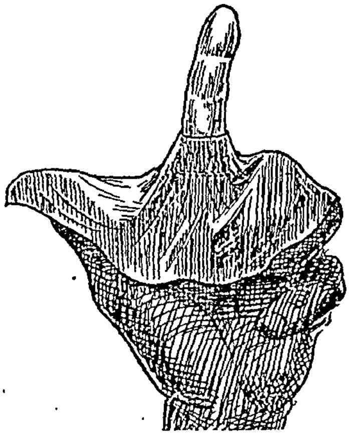
SHIELD FOR PROSTATIC EXAMINATIONS

William S. Ehrich, M.D., Evansville, Ind.

The following is a description of a very simple but exceedingly useful little device to protect the hand in the none too pleasant examination and massage of the prostate gland.

A piece of ordinary dentist's rubber dam is cut in a circle which will have a diameter of 5 inches. Through the center of this, a hole three-eighths inch in diameter is made.

After an ordinary finger cot is slipped on, the finger is pushed through the center hole, which, of course, fits snugly, leaving a margin of at least three-sixteenths inch overhang. This makes a joint which is waterproof, holds the cot firmly, preventing wrinkles, and absolutely protects the knuckles from any dirt on the external parts.



Shield for prostatic examinations.

The shield is easily and quickly made, easily cleaned, and costs practically nothing.

A RELIABLE METHOD FOR TABLE MICROSCOPIC DIAGNOSIS

B. T. Simpson, M.D., Buffalo

Pathologist, State Institute for the Study of Malignant Disease

From the fact that many men who have visited our institute knew nothing of this method, and that "table diagnosis" is in disrepute by many surgeons, it seemed worth while to publish this technic, which I have been using for the past three years. I was led to adopt it by finding that by the usual method of freezing the unfixed tissue, and staining by polychrome methylene blue, sections were sometimes unsatisfactory, and that a diagnosis given in one case was found to be incorrect when further sections were made on fixed tissues.

It seems to me that a great fallacy in making diagnoses at the table is the necessity of returning the report within three minutes. The surgeon expects to take his time with his operative procedure, while he expects the pathologist to be limited to a minimum time, and also to take the responsibility of the extent of the operation and the chances of the future of the patient. After my first mistake I refused to use the three-minute method, and frankly told the surgeons that I did not believe I could make a reliable diagnosis under eight minutes. I am happy to be able to say that, in the three years' experience with the following method, the table diagnoses have been confirmed in every case by further examination by the usual laboratory methods.

The method is as follows: Just before the surgeon is about to remove the tissue, a large test tube, about 2.5 cm. in diameter, containing about 40 c.c. of liquor formaldehydi, is brought to the boiling point and set aside. The removed tissue is laid on a dissecting board and cut with a sharp knife into sections about 5 mm. thick; these are carefully examined for suspicious areas, the selected piece is cut in a square 1.5 cm., put in the liquor formaldehydi, which is heated and allowed to boil for about thirty seconds, the tissue is now put in cold water for a few seconds, and then sectioned on the freezing microtome in the usual way. The sections are stained for half a minute in Harris acid hematoxylin and transferred in a weak solution of ammonia to bring back the blue color, then are run up through 50, 85 and 95 per cent. alcohols, then into 100 per cent. alcohol saturated with alcoholic eosin, then into carboxylol, put on the slide, blotted with filter paper and mounted in balsam. The section obtained by this method is usually as good as any frozen section obtained by the usual laboratory method.

SOME NEW INSTRUMENTS TO SIMPLIFY THE MODERN TONSILLECTOMY OPERATION*

Francis W. Alter, M.D., Toledo, Ohio

With the multiplicity of instruments already devised for the enucleation of tonsils, one must indeed have a good deal of assurance to bring out something new along these lines. I have felt, however, that the instruments which I am presenting possess sufficient merit to warrant bringing them to the notice of the profession. The combination of instruments which I am presenting has been in use for the past two years, long enough to obtain data as to their practicability and reliability.

The three instruments and devices which I have used for over two years in tonsillectomy are a mouth gag, with a successful *lip retractor;* a *tonsil-seizing* forceps combined with a tongue depressor; and a suction apparatus, with a cut-off.

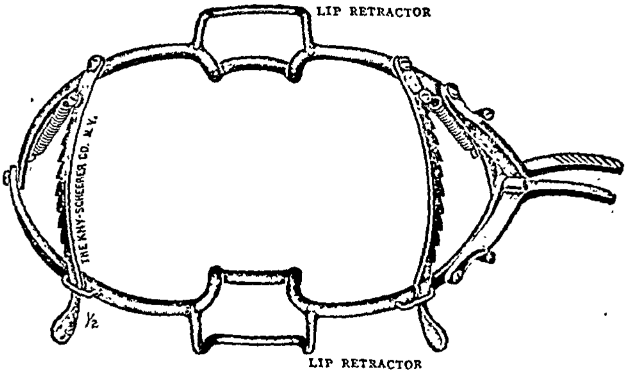

Fig. 1.—Mouth gag with lip retractor.

Figure 1 illustrates the mouth gag, which is a Whitehead gag, with the additional lip retractor. I have had as much trouble with the patient's lips getting pinched prior to the use of this instrument, as the average throat operator.

Figure 3 illustrates the combined tonsil-seizing forceps and tongue depressor, and it has the advantage that it eliminates the assistant whose duty it has been to hold the tongue depressor in position. This combined instrument has the decided advantage of depressing the tongue in the corner of the mouth just where the tongue needs to be depressed.

As will be seen, the lower finger loop of this instrument is open. It has been made this way in order that the snare wire can readily be slipped through this opening and over the upper finger loop.

---

* Owing to lack of space, several illustrations are omitted from The Journal. They are included in the author's reprints.

Figure 5 illustrates the suction apparatus. This is an instrument which certainly has a decided field in the modern operation of tonsillectomy. The instrument can be fitted to an ordinary water faucet, and a gage attached to the jar registers the vacuum pressure in the demijohn.

The main advantage of this device is in the manner of working of the suction portion. This part acts as a suction when the small piston at the end is pressed with the thumb, and shuts off the suction when the thumb pressure is released.

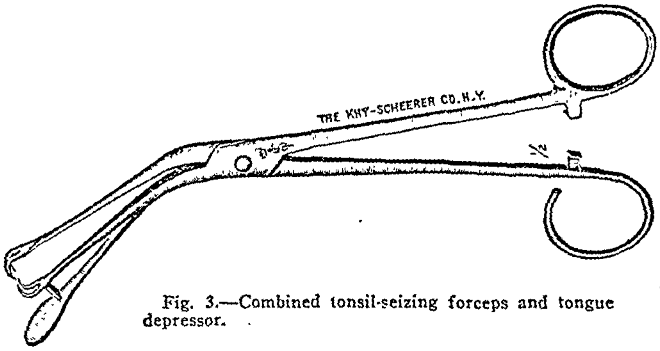

Fig. 3.—Combined tonsil-seizing forceps and tongue depressor.

In the use of this instrument it makes a true bloodless operation. There is no sponging in the throat and consequently less postoperative edema and soreness. It is an excellent device for drawing the uvula well out of the field of the snare wire.

It has the decided advantage that it can be placed in the field of operation, and in spite of oozing, the work can proceed without interference or interruption. It also has the additional advantage of making an even anesthetic and hence less danger of shock and anesthetic calamity through reflex stimulation of the vagus.

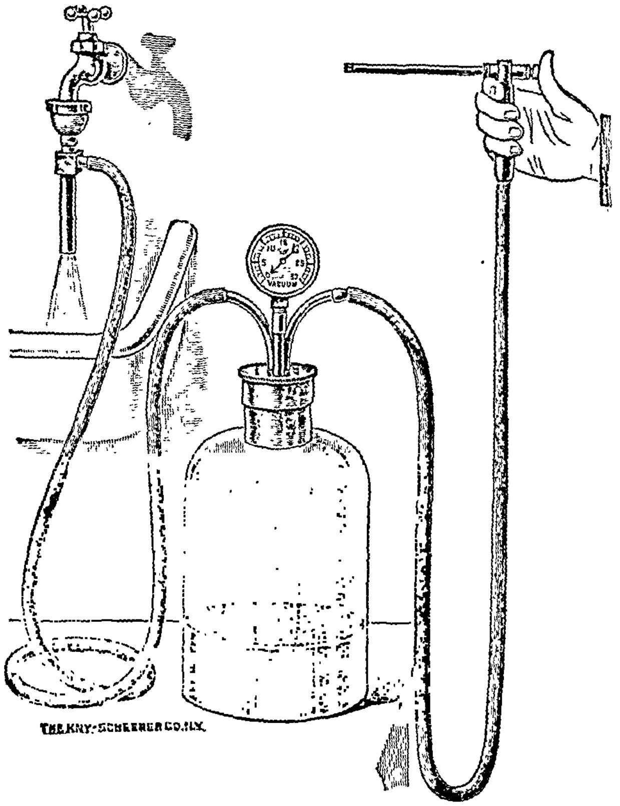

Fig. 5.—Suction apparatus complete, showing the method of holding the cut-off.

PRACTICAL PHARMACOLOGY *

(Continued from page 1849)

XXII

EVACUANTS—(*Continued*)

Evacuants may be classified conveniently for study as follows: (1) those acting mainly on the small intestine; (2) those acting mainly on the colon; (3) those acting on the small and large intestines including alkaloidal evacuants; (4) those acting on the rectum; (5) miscellaneous measures for inducing purgation.

1. *EVACUANTS ACTING MAINLY ON THE SMALL INTESTINE*

Oils

Neutral fats and saponifiable oils like butter and olive oil pass practically unchanged through the stomach, but are saponified more or less completely in the small intestine, and the resulting soaps may be sufficiently irritating to the intestinal mucous membrane to cause increased peristalsis and with an excess of the fat or oil act as a mild laxative.

Castor oil, which consists largely of ricinolein, yields a soap that is much more irritating and prompt in its action. The direct influence of the irritation is usually limited wholly or mainly to the small intestine, because these soaps are absorbed into the circulation without reaching the colon. The increased peristalsis in the small intestine rapidly drives a large amount of fluid into the colon, distending it and causing an evacuation before the stools become fully formed, or at least while they are still soft, because a sufficient interval of time is not afforded for as much fluid to be absorbed as usual.

Castor oil acts mildly even in fairly large doses, because the ricinoleic acid is liberated slowly, and the more active the peristalsis the less is the time allowed for the further liberation of the acid, hence, to a certain extent, its action is self-limiting.

THERAPEUTIC USES

Castor oil is used frequently for children, being a dependable laxative or purgative which may be administered without fear of causing intestinal inflammation or disturbing the stomach seriously, but it is not suited for continued use in chronic constipation because of its gradually lessening effect. It is also applied to the skin and to the eye as a demulcent.

The dosage is 15 c.c. (4 fluidrams). The taste is disagreeable, and children manifest an especial repugnance for it, so that it is best administered in such a way that the taste is masked.

Because of its disagreeable taste castor oil is given preferably with pungent, freely frothing beverages, or enclosed in soft gelatin capsules holding about 1 teaspoonful. It may also be administered in the form of a mixture or emulsion and this latter type of administration is becoming popular. The following may be used as a type formula:

	gm. or c.c.	
Benzosulphinid (saccharin).....	0 05	1 grain
Oil of Cloves.................	0 2	3 drops
Oil of Cinnamon...............	0 3	5 drops
Alcohol	4 0	1 fl. dram
Castor oil............q. s. ad	100	3 fl. ounces

---

* This is the twenty-second of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

In making this mixture, the benzosulphinid oil of cloves and oil of cinnamon should be dissolved in the alcohol and this in turn added to the castor oil.

Croton oil contains some free crotonoleic acid, which is irritant to the body tissues, hence it irritates the throat and stomach unless measures are taken to prevent it, and it may give rise to nausea and vomiting. It is decomposed in the small intestine, with the formation of crotonoleates. These are far more actively irritating than the ricinoleates, and croton oil causes more violent peristalsis than castor oil; but it may induce intestinal inflammation without purgation.*

THERAPEUTIC USES

Croton oil finds its special field of usefulness in mania and coma, when a prompt evacuation of the bowels is desired.

Its irritant action in the stomach, and the possibility of its causing severe intestinal inflammation limit its use as an evacuant to those cases in which the administration of a rapidly acting drug in small amount is necessary.

The dosage is 0.05 c.c. (1 minim). It may be administered in drop doses placed well back on the tongue, in the form of a pill made with breadcrumb or other absorbent, or diluted with a bland oil and given in a gelatin capsule, or simply dropped on a small lump of sugar which should be swallowed quickly.

Resin Anhydrids

There are many vegetable drugs which contain glucosidal acids, or anhydrids, which induce purgation in much the same way that castor oil and croton oil do. The drugs of this group, as a rule, are only slightly irritant to the stomach, but they become much more actively irritant in the presence of bile and when they reach the intestine cause increased peristalsis. The action of small doses is limited to the small intestine mainly but large doses often cause gastric irritation, with nausea and vomiting, and in addition to the effect on the small intestine some of the drug passes into the colon, causing pain, tenesmus and watery evacuations. Very large doses may cause bloody stools, collapse and even death. Moderate doses of these drugs cause little or no pain, but active peristalsis in the small intestine is accompanied by sounds and sensations due to the movements of fluid and gas.

THERAPEUTIC USES

All the members of this group except podophyllum and its resin are used to secure prompt evacuation of the bowels, and all of them are capable of causing profuse watery stools. Their actions are quite similar, differing only in minor details, hence it is often a matter of no great importance which of the drugs of the group is used in a given case.

They are used for the removal of fluid in dropsical conditions, especially as a preliminary to the use of digitalis and other drugs which promote diuresis. They were formerly used much more for this purpose than at present, and many physicians have abandoned their use in this way because of the dangerous depression which they sometimes cause in those suffering from cardiac diseases, and in asthenic and anemic patients.

These drugs, in doses sufficient to cause watery stools, remove fermenting and putrefying material, as well as bacteria, from the intestinal tract, and repeated catharsis may render the bowel almost sterile for a time perhaps, but large doses of such irritants may injure the natural protective powers of the intestine against bacteria and permit the latter to grow more rapidly than before.

Colocynth extract, resin of jalap or elaterin may be used for the removal of poisons which have passed through the stomach into the intestine, especially when the poison has been taken in a slowly absorbable form (belladonna berries). The action of podophyllum is usually elicited too slowly for this purpose.

The severe irritant action of these agents contraindicates their use in the presence of severe inflammation of the intestine, and large doses are contraindicated in menstruation and in pregnancy, but small doses have practically no effect on the uterus, and may be used without fear of inducing miscarriage or abortion.

The resin anhydrids are sometimes used for the removal of hard dry masses of feces which have been allowed to accumulate in the colon, because of the large amount of water which they drive into that organ. It is more rational to administer a suitable enema when such masses are to be softened, because they do not take up liquid rapidly, and even violent peristalsis may be insufficient to force them through the anus if they are formed into large masses.

Different members of this group have been recommended for the treatment of chronic constipation, and while they are useful at times, it should be remembered that constipation is a symptom of some other condition. It is better to determine the nature of the cause and direct one's efforts toward relieving it than to use the same method of treatment in every case because of the presence of a single symptom. It is impossible to enumerate here any considerable number of the causes of chronic constipation, but it is probable that its ultimate cause may be found in any one of a large number of habits, or minor derangements of various organs. It has been explained that the diuretic action of tea and coffee may augment chronic constipation by increasing the viscosity of the blood; excessive sweating may do this also. The habitual taking of an insufficient amount of water between meals is a common cause, and at least six glasses of cold water should be taken during the day in addition to any liquid that may be taken at meals. An even larger allowance should be taken if one drinks much tea and coffee, provided that this causes diuresis; or if one sweats a great deal. One is apt to suppose that any loss of water from the body in the urine and sweat is quickly made up through the amount taken for the relief of thirst thus induced, and while this is ultimately true, the amount of water in the circulation and tissues varies quite considerably from hour to hour.

An insufficient, or poorly regulated diet, is probably the commonest cause of chronic constipation, even the value of open air exercise being due largely to the increased appetite, as well as to the improved circulation and consequent secretion of digestive juices.

The trouble usually lies in the sluggishness of the large intestine, whether this be due to an atonic condition of its musculature, or to the lack of bulk in the contents received from the ileum, but the choice of the remedy may be governed by the necessity of avoiding irritation in that part of the intestine which is the seat of inflammation; for example, one would not use an irritant to the colon in the presence of appendicitis, even after the symptoms have begun to abate. It is conceivable that muscular atony may be the cause of disturbance in one case, while another presenting much the same clinical picture may be due to some disturbance in Auerbach's plexus.

---

* Owing to lack of space the materia medica o. this group is omitted from The Journal. It will be included when this series is published in book form.

DOSAGE

Colocynth is not used in substance; the extract is laxative in doses of about 0.03 gm. (½ grain) and drastic in somewhat larger doses, but nearly all evacuants vary widely in their action on different individuals, and with the same individual at different times. One reason for this is that there are all degrees of inertia of the bowel to be overcome, and just as constipation is due to so many different causes, the dose of any given drug to correct it will vary. It is true, however, that any individual who suffers from chronic constipation, or even from occasional attacks, will usually require approximately the same dose to relieve it at different times. Hence the doses given for the purgatives are approximate only, and the drastic dose for one will be merely laxative for another. In the absence of experience as to the dose required for a given patient it is well to give a small dose at first and repeat it in from four to six hours if necessary, except in the case of podophyllum. Drastic doses are not recommended.

The compound extract of colocynth contains extract of colocynth, aloes, scammony and soap, and belongs to the group which acts on the small and large intestines. It is given in doses of 0.5 gm. (7½ grains). It is much used in the form of the official compound cathartic pill,[2] which is recommended only for its effectiveness.

The dose of elaterin is 0.005 gm. (1/10 grain).

Jalap is seldom used in substance alone, but the dose is stated as 1 gm. (15 grains). The compound powder of jalap, containing potassium bitartrate, acts as a saline, as well as a resin anhydrid.

Podophyllum is seldom given in substance; the laxative dose of the resin of podophyllum is about 0.005 gm. (1/10 grain), the purgative dose is about 0.015 gm. (¼ grain).

Drugs belonging to the group of resin anhydrids are preferably administered in the form of pills or massed and enclosed in gelatin capsules.

2. *EVACUANTS ACTING MAINLY ON THE LARGE COLON*

ANTHRACENE DERIVATIVES

The drugs of this group are said to belong to the group of anthracene, or anthraquinone, derivatives because the crude drugs of the group depend for their evacuant action on one or more substances which may be considered as derived from anthracene ($C_{14}H_{10}$) or from a derivative of it called anthraquinone ($C_{14}H_8O_2$) which differs from anthracene by having two CO groups uniting two benzene rings, whereas in anthracene the rings are united by two CH groups. Hydroxyanthroquinone has an OH replacing an H of anthraquinone, and several hydroxyanthroquinones are present in different drugs of this group. Among the most common are di-hydroxy-anthroquinone, or emodin, and tri-hydroxy-anthroquinone, or chrysophanic acid.

Emodin is present in all the crude drugs of this group, it and other closely related bodies being formed by the decomposition of glucosidal bodies which are present in larger amount in the crude drugs.

These hydroxyanthroquinones pass through the stomach and small intestine causing no irritation and exert their specific action on the colon. They cause purgation after the lapse of about sixteen to twenty hours following their administration in most cases.

Small doses cause normal evacuations attended with little or no colic; larger doses cause soft, or watery stools, which may be preceded by severe colicky pains. This irritant action on the colon contraindicates their use in menstruation and in pregnancy, because they induce reflex irritation in the uterus, increasing the menstrual flow when menstruation is in progress, or tending to cause expulsion of the fetus during pregnancy. It is possible that they also act directly on the nerves supplying the uterus. The action which contraindicates their use during menstruation indicates their employment as emmenagogues when it is desired to institute the flow.

Aloes contains about 10 per cent. of aloin which belongs to the hydroxyanthroquinone group. Aloin is inactive itself but is changed into an irritant amorphous substance in the colon, and on this decomposition product the purgative action depends. The formation of this decomposition product is facilitated by the presence of alkalies and iron, hence aloes and aloin are frequently administered with soap and iron.

Aloes is especially prone to cause uterine contractions, probably because the aloin is absorbed in part and acts directly on the uterus, hence purgative doses of aloes are especially contraindicated in pregnancy, but it is the most frequently used of the group for its emmenagogue action. Aloin, after its subcutaneous injection, is excreted into the large intestine causing purgation, but the injection is painful.

Fresh cascara sagrada contains emodin and also a ferment having an emetic action, but this ferment is gradually destroyed when the drug is stored. It also contains a bitter principle which may be utilized as a tonic but the taste is so disagreeable that many prefer to use a preparation in which the taste is masked, or one from which the bitter has been removed in part.

Rhubarb contains chrysophanic acid and emodin. The chrysophanic acid is quite irritant, but it is absorbed without reaching the colon, hence it does not participate in the typical rhubarb action. The irritant action of chrysophanic acid is utilized therapeutically as an application to the skin in the form of chrysarobin ointment, chrysarobin being a compound of chrysophanic acid. Rhubarb also contains tannin; hence it is astringent in small doses, laxative in large, and the astringency tends to assert itself after the laxative effect has been induced. It sometimes causes nausea and headache. The aromatics present in the aromatic syrup enhance the astringent effect.

Senna contains emodin and a bitter resin, which is removed by percolation with strong alcohol before preparing the fluidextract and the syrup. This treatment does not impair the cathartic action of the preparation but it renders it much less disagreeable to the taste and prevents the griping to a large extent.

PHENOLPHTHALEIN

The action of phenolphthalein is much like that of the other hydroxyanthroquinones over which it appears to possess no very decided advantage; it is capable of giving rise to poisoning when overdoses are used.

---

[2] This preparation is a survival of the "shot-gun" type of mixtures; there is a rational basis, perhaps, for the employment of two evacuants having different seats of action, but there is no apparent advantage in using together two substances having such similarity of action as colocynth and scammony.

DOSAGE

The laxative dose of aloes is from 0.03 to 0.05 gm. (½ to 1 grain), the purgative dose (which is not recommended) is from 0.15 to 0.3 gm. (2 to 5 grains). As an emmenagogue the larger dose is employed. Aloes, the extract of aloin, is commonly used with extract of belladonna or atropin in the treatment of chronic constipation, but the continued use of atropin even in small doses is not certainly free from objections, and there seems less reason for its use with small doses of these drugs than with the larger ones used for active purgation. The official compound laxative pill, which is practically identical with certain proprietary preparations, contains 0.8 mg. (1/80 grain) of extract of belladonna, representing about 1/10 mg. (1/650 grain) of atropin. This dose of atropin is probably without material effect on the intestine when a single dose is taken, but the possibility of its disturbing the digestion when long continued is worthy of consideration. The compound laxative pill also contains strychnin and ipecac. The aloin alone in the form of a pill will often act quite as well as the more complex mixture.

To avoid gastric irritation aloes and aloin are preferably administered in the form of pills or, like the drugs belonging to the group of resin anhydrids, massed and enclosed in gelatin capsules. For making the necessary mass it has long been a practice to use soap or one of the gum resins like myrrh or asafetida which have the additional advantage of being somewhat aromatic.

Typical combinations for pills of aloes are included in the several pharmacopeias, the only objection to them being that they are set formulas instead of being adapted to the case in hand. They serve, however, to illustrate the combinations that have been used.

Aloes may be prescribed somewhat as follows:

	gm.	gr.
Aloes	1.3	20
Soap	1.3	20
Mix and make into 10 pills.		
Aloes	1.3	20
Myrrh	0.6	10
Powdered Glycyrrhiza	0.6	10
Syrup a sufficient quantity.		
Mix and make into 10 pills.		
Aloes	1.0	15
Asafetida	1.0	15
Soap	1.0	15
Mix and make into 10 pills.		

The dose of extract of aloes is only slightly smaller than that of the aloes itself, and there are no sufficient reasons for the use of this preparation. The laxative dose of aloin is from 8 to 20 mg. (⅛ to ⅓ grain). Phenolphthalein is given in doses of 0.05 to 0.5 gm. (1 to 8 grains) in capsules or cachets. Larger doses are not to be recommended in case this is not effective. Cascara sagrada is practically never given in substance; the fluidextract and the aromatic fluidextract may be given in doses of 0.6 to 2 c.c. (10 to 30 minims), the smaller dose is for repetition several times daily, the larger dose is given after dinner or at bedtime, preferably so that the action may be induced the next morning. The dose of the extract of cascara sagrada is from 0.1 to 0.5 gm. (2 to 8 grains). One should aim to use the smallest dose which is effective, and reduce this from time to time.

Rhubarb is sometimes used in the form of the powder, or one may obtain the drug in the form of "cubes" or "fingers" which are carried conveniently when it is desired to take several doses during the day. The laxative dose of rhubarb is about 1 gm. (15 grains) or more; with smaller doses—0.1 to 0.3 gm. (1½ to 5 grains) the bitter and astringent actions only are obtained. The dose of the extract of rhubarb is about one-fourth that of the crude drug. The dose of the aromatic tincture is about 2 c.c. (30 minims) and that of the aromatic syrup about 8 c.c. (2 fluidrams). The cathartic dose of senna is about 4 gm. (60 grains) in the form of powder or infusion. The dose of the compound powder of glycyrrhiza (in reality a preparation of senna) is 4 gm. (60 grains). The fluidextract is given in doses of 2 c.c. (30 minims) and the syrup in doses of 4 c.c. (1 fluidram). This dose of the syrup is only half as active as the dose given of the fluidextract.

THERAPEUTIC USES

The evacuants of this group are widely used in small doses as laxatives in the treatment of chronic constipation. Aloes, or aloin and cascara sagrada being especially valuable for this purpose. Cascara often exerts a tonic action on the intestine, permitting of a gradual diminution and stopping of the dose as the intestine regains its normal function.

The irritant action of the drugs of this group is so slight that they may be used in small doses for long periods without giving rise to inflammation, and the colon does not appear to habituate itself to their action, so that the same dose may continue to be effective for years. It is true, however, that with increasing obstinacy of the constipation larger doses are often called for in time, but this is rather from an augmentation of the condition which gave rise to constipation, and not from habituation to the drugs of this group.

Cathartic doses of aloin and aloes are not especially to be recommended, cascara sagrada or senna being preferred in such cases. One of the most effective of the common cathartic mixtures is the old time compound infusion of senna (senna, 6; manna, 12; magnesium sulphate, 12; fennel, 2; water to make 100), which acts on the large intestine and in addition promotes peristalsis in the small intestine by preventing absorption of fluid.

Rhubarb is used in the earlier stages of diarrhea to remove irritating substances and then to check intestinal movements; the aromatic syrup is especially adapted for children.

SULPHUR

One of the important irritants for promoting peristalsis in the large intestine is hydrogen sulphid formed in the course of decomposition of sulphur-containing substances in the large, and also in the small, intestine. The production of hydrogen sulphid can be materially increased by the administration of sulphur through the action of micro-organisms and albuminoids, more particularly the protein substances present in the small intestine. Sulphur is not affected in the stomach. A portion of the hydrogen sulphid formed is absorbed, some of it is oxidized further and eliminated with the urine as sulphates and a portion not so oxidized is eliminated by the skin and the lungs as hydrogen sulphid. The latter rather objectionable feature has no doubt had much to do with the decline in the use of sulphur as an evacuant.

DOSAGE

Sulphur, because of its insolubility and practical inertness, may be administered in liberal doses; 4 gm. (60 grains) being frequently given. It is still used in medicine in the form of the compound powder of glycyrrhiza referred to under senna.

NEWER KNOWLEDGE REGARDING INTESTINAL OBSTRUCTION

The search for the cause of the symptoms and death which frequently attend intestinal obstruction has called forth the efforts of some of the most representative American laboratories in the attempt at an elucidation. At present there is an agreement on some of the features of the situation and a few apparent contradictions in respect to others. Few complex problems of immediate surgical interest have been attacked with greater intelligence and promise of solution. The symptomatology and pathology of intestinal obstruction have been considered from many angles, until today it seems possible to make certain general statements which are likely to improve greatly the surgical treatment of a serious condition. One group of investigators has emphasized the loss of body fluids as a factor in the causation of death; another has pointed out the damage to the intestinal mucosa which must usually be reckoned with; still others have directed attention to the rôle of the ensuing interference with the circulation in the obstructed bowel, and to the opportunity which this offers for an unusual performance on the part of alimentary bacteria.

Interesting though the history of this chapter of medical research may be, there is little practical advantage at this time in reviewing the steps in the direction of the progress made. Most, if not all, of the observers believe that the serious symptoms and death are the result of a toxemia. Where and how the responsible toxin is produced and absorbed has not been so easy to determine. In the words of the most recent contributors in this field, "When the problem of intestinal obstruction is reduced to its fundamentals, it seems that there is not such a wide difference of opinion between the experimental workers, except as to the source and the physical and chemical characteristics of the toxic material which is responsible for the symptoms and death, the apparently contradictory statements being more the result of undue emphasis on different factors, and the failure to distinguish clearly between the production and absorption of the toxin."

To a certain extent, Murphy and Brooks[1] of the Washington University Medical School have reconciled the conflicting opinions.[2] The toxins which are present in the content of the obstructed bowel and which, when absorbed in sufficient amount, produce the definite pathologic lesions, are the result of bacterial growth. It has been possible, after continued drainage, to obtain a jejunal loop which was sterile. Occlusion of this failed to produce the usually expected death; and the accumulated fluid was not toxic as it ordinarily is when bacteria are present. The toxins are not specific for any part of the intestinal tract, as was earlier believed by some of the investigators. Following the obstruction and interference with the nutrition of the gallbladder containing intestinal bacteria, symptoms identical with those of intestinal obstruction may be observed. The contents of such a gallbladder, even after sterilization, produce symptoms and a pathologic picture identical with that following the injection of the content of an obstructed segment of intestine. A sterile gallbladder, however, can be obstructed up to the point of complete gangrene without the appearance of symptoms or the development of toxic contents.

The toxic substance does not pass through a normal mucous membrane. This is a fact of major significance, so that in the production of harmful effects, the factors which make absorption possible are of more importance than those which produce toxin. Interference with the circulation of the obstructed intestine helps to institute the damage that permits of abnormal absorption. It has been puzzling to find that simple obstruction of a segment of the duodenum or jejunum results in earlier or severer symptoms than similar obstruction of the ileum. It appears, however, that the more abundant secretion into the upper bowel leads to a more rapid distention and consequent circulatory disturbance of the bowel wall. The toxin may enter the circulation by way of the thoracic duct.

It is still too early to generalize about the nature of the poisonous substance. Its chemical and physical characteristics are stated to vary with the duration of the obstruction. The effects in respect to symptoms and lesions produced seem to resemble those attributed to so-called ptomains.[3] The outcome of the foregoing studies already furnishes valuable guidance in a practical way. In the surgical treatment of cases of intestinal obstruction, that part of the intestine with a mucous membrane which has been so damaged as to permit of abnormal absorption should be resected rather than drained. The restitution of the body fluids lost must also not be neglected.

THE USE OF ALKALIES IN ASIATIC CHOLERA

It is not far from the truth to say that until recently the treatment of cholera has been essentially expectant and symptomatic. Specific antiseptic substances administered by mouth to inhibit the growth of the infecting organisms in the alimentary tract have been without value. Attempts have been made sometimes to expel the bacterial invaders by the use of purgative drugs. Yet such procedures fail to bring any relief whatever to some of the consequences and complications that attend the original intoxication. Prominent among the latter are the renal lesions, not infrequently accompanied by uremia.

Dr. A. W. Sellards[1] of the Johns Hopkins Hospital, who has had an extensive experience in the treatment of cholera in the Far East, has lately pointed out that some of the symptoms of uremia which resemble toxemia are due, *not to the presence of a foreign* toxin, but to the depletion of a normal constituent of the blood. In cholera, according to Sellards, there is a greatly increased tolerance to alkali bicarbonate. This tolerance, however, is not specific for the nephritis of cholera. It occurs not only in nephritis arising from other infections, but also in the nephritides which are free from infection. In this respect, therefore, there is a close relationship between the renal lesions of Asiatic cholera and the ordinary forms of acute and chronic nephritis. In renal disease (chronic interstitial nephritis and primary contracted kidney) a group of clinical symptoms, including dyspnea, changes in the alkali content of the blood, and decrease in its quota of carbon dioxid, reach their height during the stage of uremia. Similarly uremia, which follows the common renal disturbances of cholera, is plainly something more than a mere intoxication. The death rate from the uremia alone has been higher than in the majority of the common specific bacterial infections.

It is at this stage of reaction in cholera, when the evidence of nephritis is becoming prominent, that a distinct *increase in the tolerance* to sodium bicarbonate develops.[2] Sellards has described it as a clinical picture of acidosis. It seems best, however, to avoid the use of this ill-defined term, which means intoxication with acid in its original sense. As Fischer remarks: The word "acidosis" has had its meaning twisted so greatly to suit the whims of different authors that it might well disappear from our medical and physiologic writings. The mere finding of various acids or "acidosis compounds" in the urine or elsewhere does not yet mean an acid intoxication. The acetone bodies of the diabetic do not betray an acid intoxication, but an altered chemistry from which an acid intoxication may result. A normal or abnormal acid may be produced in great quantities in the organism and appear in the urine, yet if sufficient base is available they are neutralized and so are practically without effect.[3] What Sellards actually implies to be the nature of the "acidosis" associated with the nephritis and uremia of cholera is an impoverishment of the sources of fixed bases in the body.

This deficiency in carbonates, with its train of symptoms ending in coma and air hunger, is conceivably attendant upon a diminished excretion of acid on account of urinary changes due perhaps to impaired functional capacity of the kidneys; or it may be attributable to loss of alkali directly by the bowel during the excessive purging that occurs. In any event, Sellards believes that the clinical evidences are sufficiently definite to constitute a rational basis for treatment of the uremia of cholera with alkalies in the form of bicarbonate. He maintains that in practice it has proved far more efficient than the use of solutions of sodium chlorid, which have been employed with some success in the stage of collapse to restore the fluid lost from the body.

Alkali therapy in cholera is not entirely new. The attempt of Sellards is in the direction of a more rational application of the principles discussed above. It is regarded as advisable to give a mildly alkaline solution (0.5 per cent. of sodium bicarbonate) early in the course of the disease, before an outspoken uremia has developed, and to increase the quantities if symptoms of uremia appear. As much as 100 grams (3½ ounces) of bicarbonate may be required in the course of two or three days. Experience in two epidemics of cholera speaks favorably for this mode of treatment.

THE TREATMENT OF INFECTIOUS DISEASES WITH THE SPECIFIC SERUM OF CONVALESCENTS

Shortly after the discovery of diphtheria antitoxin, numerous efforts were made to find antitoxins for various other infectious diseases, as it was believed that the principle illustrated by the treatment of diphtheria with antitoxic serum was one of general application. It soon was learned, however, that only in diphtheria and tetanus is recovery dependent on the direct neutralization of definite toxins by specific antitoxins. In the course of this search for specific methods of treatment it was proposed to use the serum of convalescents from attacks of certain familiar infectious diseases. Thus, Weissbecker[1] tried the subcutaneous injection of 10 c.c. of the serum of convalescents in measles, scarlet fever, typhoid fever and pneumonia, reporting good effects especially in the latter disease. He reasoned that recovery from these diseases is the result of a natural immunization, and that consequently the blood of convalescents may be assumed to contain specific antitoxins or, more broadly, specific antibodies.

Huber and Blumenthal[2] were impressed favorably with the effects of specific convalescent serum in scarlet fever, measles and pneumonia, and von Leyden[3] described sixteen cases of scarlet fever treated in this way, in three of which crisis occurred immediately after the injection of the serum, the quantity of which varied from 10 to 20 c.c. In one case the development of the rash was arrested. Von Leyden makes no mention of the exact time after the attack when he obtained the serum. This report was followed during the next year by a few further reports mostly with "good results"; but now the method fell into abeyance until 1912, when Reiss and Jungmann[4] described their results in cases of scarlatina gravissima.

Reiss and Jungmann used serum obtained about the end of the third week after the onset, injecting from 50 to 100 c.c. intravenously. Twelve cases are described, all injected not later than the fourth day, and in all there followed a rapid improvement as by crisis within fourteen hours or so, which was in marked contrast to the course in cases not so treated, in which recovery by crisis occurred only occasionally. The serum did not seem to have any effect on secondary infection. In some cases the rash faded away immediately after injection of the serum. Koch[5] reports on twenty-eight additional cases, treated with convalescent serum in the same hospital. Only one death occurred, and in that case the patient was moribund when admitted. Koch emphasizes that in this series of extremely severe, toxic scarlatina, hemorrhagic nephritis did not develop, that the improvement in many cases was as striking as that seen in diphtheria after injection of antitoxic serum, and that the serum must be injected intravenously in quantities not less than from 50 to 100 c.c. even in small children, and not later than the third day. Koch also reports good effects in twelve cases injected intravenously with normal human serum, and Rowe[6] was unable to convince himself that there were any different effects in cases treated with normal and with convalescent serum. Koch, however, states that the superiority of convalescent serum is seen clearly in the very severely toxic cases with coma and cool and bluish skin. In order to secure the best effects, the mixed serum from several convalescents is used after it has been stored for some time. The serum should be obtained about twenty-one days or thereabouts after the onset. The most rigid tests must be used to determine freedom from tuberculosis and syphilis on the part of the donors, and the sterility of the serum established by cultural methods. In hospitals for scarlet fever there need be no difficulty in having on hand suitable serum from convalescents. Koch suggests that such serum be reserved for the gravest cases, and that otherwise normal serum be used. As yet no explanation is offered of the alleged benefits of normal serum. Schultz[7] believes he has shown that the effect does not depend on lipoids that are extracted in the cold.

Netter[8] recently has used the serum of persons who had had poliomyelitis in the treatment of the acute attack, giving the serum intraspinally in small doses repeated daily. He says the results were good.

If we ask what we can expect from this method of specific treatment, the answer must be that only by continued critical observations can its value be determined. Certainly the results described in the severe toxic forms of scarlet fever fully warrant extended trial under suitable conditions, and that would mean in hospitals where convalescent serum can be kept on hand in such mixtures as are most likely to insure some specific antiscarlatinal virtues. Where such serum is not obtainable, there certainly is no reason why sterile, nontoxic, normal human serum may not be tried in severe and desperate cases.

THE SIGNIFICANCE OF THE PUPILLARY REACTION TO EPINEPHRIN

When a solution of epinephrin is instilled into the conjunctival sac, no noteworthy effect is produced on the pupil of the eye. After complete excision of a superior cervical ganglion of the sympathetic nervous system, however, similar introduction of epinephrin causes a dilatation of the pupil on the operated side. This was demonstrated by Meltzer[1] at the Rockefeller Institute for Medical Research in 1904. The degree of pupillary dilatation depends on the quantity instilled. It can easily be made maximal and may last for some time. The myotic effect of physostigmin is also overcome by instillation of epinephrin.

The dilatation of the pupil is accomplished by the contraction of a muscle, the dilator pupillae, just as the constriction of the pupil is accomplished by the contraction of the constrictor pupillae. These muscles are exact antagonists. When one is contracted the other is relaxed; and it seems to be an established conclusion that the relaxation is an active one, so that the changes noted at any time can take place promptly, rather than gradually. According to Meltzer's view, the normal effect of the superior cervical ganglion is to inhibit the dilator and to stimulate the constrictor, and the effect of suprarenal extract is just the reverse of it, that is, to excite the dilator and inhibit the constrictor. Epinephrin can, therefore, show its proper effect only after the antagonistic activity of the ganglion is removed.

J., and Auer, Clara Meltzer: Studies on the "Paradoxical" Pupil-Dilatation caused by Adrenalin, I, The Effect of Subcutaneous Injections and Instillations of Adrenalin upon the Pupils of Rabbits, Am. Jour. Physiol., 1904, xi, 28; II, On the Influence of Subcutaneous Injections of Adrenalin upon the Eyes of Cats after Removal of the Superior Cervical Ganglion, ibid., p. 37; III, A Discussion of the Nature of the Paradoxical Pupil-Dilatation Caused by Adrenalin, ibid., p. 40.

We have reviewed these physiologic investigations in some detail in order to afford an interpretation of the observation made by Loewi,[2] in 1908, that instillations of epinephrin produce dilatation of the pupils in animals after excision of the pancreas also. Loewi based an explanation of this mydriasis on the facts already cited. He assumed that the pancreas exerts an inhibitory influence on the sympathetic system, so that the removal of the gland would bring about a situation comparable to that noted after extirpation of the cervical ganglion. After either procedure the introduction of epinephrin into the conjunctival sac can induce mydriasis. Loewi attempted a practical application of these phenomena by examining the pupillary responses of persons suffering from various diseases, particularly diabetes. The discovery of positive mydriatic reactions after epinephrin instillations in several of these cases suggested this as an indicator of pancreatic involvement. The reaction has accordingly been proposed as a test for pancreatic disease, and particularly diabetes of pancreatic origin.

It is now reported by Loewy and Rosenberg[3] that the mydriatic reaction of Loewi can be brought about in any condition in which there is an excess of sugar circulating in the blood. Not only can the characteristic pupillary response to epinephrin be produced whenever hyperglycemia results in animals after intravenous infusions or even liberal ingestion of glucose, but it also ensues when the sugar level of the blood is raised by certain drugs. The Loewi phenomenon, therefore, cannot be correlated solely with the pancreas, except on the improbable assumption that this gland becomes involved in every condition of hyperglycemia. The reaction can no longer be regarded as a characteristic test of pancreatic function.

In the hypoglycemia produced by phlorizin, the mydriatic response to epinephrin cannot be obtained, despite the prominence of the resulting glycosuria. Perhaps we may now assume that an excess of sugar in the blood directly affects the sympathetic inhibitory factors. It remains to be determined by clinical studies whether the pupillary reaction can be used to distinguish between true diabetes with an attendant hyperglycemia and the glycosurias of renal origin in which the level of the blood sugar is not raised. The introduction of satisfactory clinical methods of blood analysis has to some degree rendered other procedures superfluous.

PELLAGRA IN BESSARABIA

In spite of the rather severe criticism to which his work was subjected at the last meeting of the Italian Pellagrologic Congress, Tizzoni apparently has modified but little, if at all, his idea that pellagra is an infectious disease due to the micro-organism which he claims to have isolated from those sick of the disease, and which he has named *Streptobacillus pellagrae* (T). Recently[1] he has reported work done by him during the past year. In addition to his bacteriologic studies, observations on pellagra were made in Bessarabia, Russia. These observations are incomplete, the war having interrupted his work; but in spite of their fragmentary character, they possess interest.

Briefly, he states that pellagra is very prevalent in Bessarabia, and that the disease shows there an intensity unknown in Italy now for many years. In one village of 3,000 population there were over thirty cases. The disease is much more prevalent in northern and central than in southern Bessarabia, but he could see no reason for this geographic restriction. Cases were not uncommon with diminished urinary secretion, bladder irritability, albuminuria and edema of the face. The disease is observed there rather frequently in infancy, sucklings at six to eight months being often stricken.

The hygienic conditions obtaining among the people are bad, the water supply is suspicious, and their food is monotonous in character, none too abundant in quantity, and of poor quality—mainly maize and that of poor grade. Their diet in large part consists of bread made of maize and wheat flour mixed, polenta, and a kind of soup or broth made from maize.

These data from Bessarabia broadly coincide with observations recorded for other places where pellagra prevails, but we also find here, as elsewhere in dealing with this disease, one or two particulars at variance with recorded observations. The prevalence of pellagra in Bessarabia, if we may judge by the one small group of people mentioned by Tizzoni, is less than that reported for some places in the United States. Even in Italy, where the disease seems to have been on the decline for some years now, there are doubtless some places which still exceed this rate. The highest recorded prevalence of pellagra in the United States is perhaps found among the mill village population of South Carolina, approximately 150 per 10,000 of population.[2] The intensity of the disease in Bessarabia would indicate, as Tizzoni appreciates, that its advent there is perhaps more or less recent. The first appearance of pellagra in a population seems often attended by severe manifestations, to be later

[1] Tizzoni, G.: Relazione sulla campagna pellagrologica per l'anno 1914, Bologna, 1915. Tizzoni, G., and De Angelis, G.: Significato ed importanza del polimorfismo dello streptobacillus pellagrae (T), Reale Accad. dei Lincei, Series 5, Vol. X, Fasc. XV, 1914.

[2] Thompson-McFadden Pellagra Commission, First Progress Report, New York, 1914; Second Progress Report, New York, 1915.

followed by a much milder type of the disease. In a general way, this is the history of pellagra in most places involved. The most obvious interpretation of such a phenomenon would be sought in a kind of acquired racial immunity, but this is not supported by the very evident fact that individual pellagrins apparently develop little immunity to the disease.

The restricted geographic distribution of pellagra in Bessarabia is quite in accord with what has been observed elsewhere. For example, southern and insular Italy have suffered from the disease practically not at all, and in the United States it is very largely confined to the South.

Cases of pellagra with renal involvement are not rare, but such marked evidences of renal inadequacy as Tizzoni reports are not common. The observation of pellagra in infants from 6 to 8 months is a striking thing. Pellagra in infants is by no means unknown, but it is certainly far from common. The frequency of this occurrence in Bessarabia is an epidemiologic observation of importance.

Bad hygienic conditions, and especially poor food have always accompanied pellagra. What factors they play in its etiology remain to be determined.

Much of Tizzoni's work during the year has been devoted to cultural studies of his micro-organism, and he discusses with considerable fulness its rather remarkable polymorphism, the micro-organism assuming numerous forms under changed biologic conditions. Indeed, he thinks he might better call it the pleomorphic streptobacillus of pellagra.

Tizzoni is a pronounced zeist in his views, holding that the infection in pellagra is derived from corn. It is interesting to note, therefore, that he admits in this paper the existence of the disease in persons who do not eat this grain. It is also of interest to note the gravity with which he, and indeed many other Italian scientists, discuss the question of pseudopellagra. This conception is largely based on the history of the case with regard to the consumption of maize, and has received scant sympathy among American students.

Tizzoni has studied pellagra for several years, and has written voluminously on his views. His observations remain, however, practically unconfirmed, and, whatever be the individual opinion as to the cause of pellagra, his presentation of the matter is not likely to meet approval in this country. Leaving aside the lack of any confirmation of his work and the very remarkable pleomorphism of the micro-organism he describes, his writings display an effort to create harmony between laboratory results and clinical and epidemiologic facts—harmony too perfect, too beautiful and too soul-satisfying. Such beautiful harmony is rarely realized in actual conditions, and its presence would, in the minds of the wary, be far more likely to produce skepticism than conviction.

One might safely venture the statement that, up to the present, Tizzoni's work has done very little toward giving material help in the solution of the etiology of pellagra. In the present state of our knowledge regarding this perplexing problem, however, we cannot well afford to abandon a safe judicial attitude, and in conformity therewith we cannot entirely neglect Tizzoni's work, however unpromising it may appear.

FACTORS DETERMINING PHAGOCYTOSIS

The mechanism of phagocytosis, that is, the engulfing of bacteria, cells, tissue products, etc., by leukocytes, is usually interpreted in terms of chemotaxis. Substances present in the environment are believed to exercise a sort of directive influence, either attractive or repellant, on the phagocytic cells. Since the stimuli most likely to reach the leukocytes from a foreign agent and bring about an alteration in their movement and performance are chemical in nature, the importance of "chemotaxis" in phagocytosis and leukocytosis is everywhere emphasized.

This familiar attempt at an explanation of the behavior of leukocytes cannot readily be applied to the undeniable phagocytosis of insoluble, chemically inert particles like coal dust or carmin granules. Leukocytes have frequently been seen to enclose these with the same avidity that they engulf bacteria. It has been surmised, without further evidence, that the foreign particles in some way acquire a coating from some component of the solution in which they are suspended, and thus acquire chemotactic properties.

In his early researches on phagocytosis, Metchnikoff interpreted the phagocyte-enhancing power of the medium as a stimulation of the leukocytes. Wright demonstrated that the essential regulating influence affecting phagocytosis rests on the action of the serum on the bacteria, when they are the factors involved. Hektoen and Ruediger[1] have furnished classic evidences of this. They showed that human leukocytes in the presence of normal defibrinated blood will take up bacteria energetically. When the leukocytes, however, are washed free of blood and added to untreated bacteria, phagocytosis is practically nil. If such washed leukocytes are mixed with bacteria that have been previously in contact with serum, active phagocytosis will take place. In other words, the bacteria have been altered by the serum in such a way that they are now amenable to phagocytosis by washed leukocytes. The serum then acts on the bacteria and not on the leukocytes.

These now familiar observations serve to remind us that the conceptions of the mechanism of phagocytosis have been altered with the progress of time. Much remains to be explained, particularly where the chemical theories fail. Kite and Wherry[2] have looked in another direction for an answer. They suggest that the amount of adhesion in a mixture of leukocytes, bacteria and unheated serum must depend on the relative stickiness of the bacteria and the leukocytes. In harmony with observations on the adhesive character of the surface of certain amebas, it is now shown that agitation of suitable mixtures of leukocytes and bacteria causes the latter to stick to the blood cells and become rolled into their substance. Experiments with a minimum amount of agitation show that here "phagocytosis" is reduced.

---

[1] Hektoen and Ruediger: Jour. Infect. Dis., 1905, ii, 132.

The rôle of the serum, which is so important in all modern chemotactic considerations of phagocytosis, is interpreted in the following way by Kite and Wherry: Foreign particles, such as carbon, are taken up by leukocytes because the latter have sticky surfaces. Bodies similar to many bacteria stick to leukocytes best in the presence of unheated serum because they adsorb something from this medium which makes them more sticky; or they are in some way rendered more sticky, and hence the chances of their adhering to the surfaces of leukocytes are increased. There is evidence that, even in the absence of serum, certain leukocytes are sticky enough to allow some bacteria to adhere. The casual reader will possibly conclude, however, that there is quite as much uncertainty in the physics of stickiness as in the chemistry of chemotaxis.

Current Comment

THE FLY CAMPAIGN IN DETROIT

The injunction to "swat the fly" has become general all over the country. To this in the last few years has been added the additional injunction to swat him early. Spring fly campaigns are now a feature of the public health work in many of our cities. An especially effective popular movement in this direction is now being carried on in Detroit, under the direction of the local board of health. Taking advantage of the human fondness for rivalry and competition, the boys of the different wards and sections of the city are being organized under one chief junior sanitary inspector and twenty-four junior sanitary inspectors. Under each inspector are from five to seven captains. Under each captain are from two to seven lieutenants. This furnishes a force of twenty-four inspectors, 125 captains and 600 lieutenants. Each lieutenant has as many patrolmen as he can enlist. In all, over 1,000 boys are enrolled in this movement. Each of these young health workers is provided with a suitable and imposing badge. Each lieutenant is provided with a map of his district which he returns, showing all manure piles, uncovered garbage receptacles, breeding places for flies and other insanitary conditions in his district. Restaurants, meat markets, milk depots, bakeries, etc., are visited at intervals, and a report is made on all the flies which can be counted in a certain number of minutes. The reports are all tabulated on a large map at headquarters, so that a comparison is always possible between different districts. The conduct of the work and the discipline of the junior force are as far as possible left in the hands of the boys themselves. This movement is an interesting illustration of the growing tendency on the part of health officers to utilize the public and to work along recognized psychologic lines. Probably every boy of from 12 to 16 desires above all things to be a policeman and to wear a badge. If he cannot fight crooks, the next best thing is fighting flies. If the enthusiasm engendered by several generations of "Old Cap. Collier" dime novels can be utilized in fighting flies or, better still, in fighting the filthy conditions under which flies breed, the public health propaganda will have gained a valuable ally.

A COUNTRY EDITOR ON SCHOOL INSPECTION

Manatee, Florida, is a town of less than 1,000 inhabitants, but evidently it has the spirit and progressiveness of some much larger communities. Discussing medical school inspection, the local newspaper, the Manatee *Record*, recently said editorially: "Medical inspection is a business proposition. In a town with 125 children, it is claimed there will be an annual saving of $2,265 if by thorough medical inspection the curable physical defects that handicap school-children could be remedied." The editor of the *Record* has grasped the essential feature and the advantages of medical school inspection. He sees no reason why modern scientific knowledge should not be utilized in administering the public schools in the most economical and efficient manner possible. Why spend the money in a well-nigh hopeless endeavor to teach children with defective eyes and ears, when at a slight expense each child could be put in the best possible condition to receive and profit by instruction? The question is a simple one. Do the taxpayers of a community wish to put their children in good physical condition, in the same way in which they would improve their school grounds, building and equipment, or do they prefer to spend their money on school equipment and leave the child defective and unable to profit by the instruction offered? The editor of the Manatee *Record* is apparently not alarmed by any specious cries of invasion of "personal liberty." In fact, it is difficult to see how the personal liberty of any one is invaded when a child's defective eyes are put into condition whereby he can see the blackboard or read his textbook without discomfort. Children's diseases also are rightly regarded by the editor of the *Record* as wasteful and unnecessary. "More and more the people of the country are realizing that it is not necessary for children to go through a course of measles, whooping cough, mumps and scarlatina. . . . Medical inspection and prompt and firm handling of parents as well as pupils will enable the majority of youngsters to enter and leave the grammar schools without having had to be a nuisance to themselves and their parents and teachers by various spells of preventable diseases." An exchange whereby different educational institutions trade professors temporarily has become a fixed institution in the educational world. What a valuable thing it would be if some of our larger cities could arrange to trade editors with Manatee for a few years. This would be a misfortune for Manatee, but it might be a godsend for some other communities.

THE MILK SUPPLY AND FOOT AND MOUTH DISEASE

It was to be expected that the extensive and serious outbreak of foot and mouth disease, again discovered in this country last October and now apparently well under control, should raise questions respecting its bearing on human health. Although only secondarily and casually a malady of man, the foot and mouth disease seems to reach him in occasional cases in connection with every epizootic. Some authorities believe that its incidence in man is much greater than the statistics indicate, as the milder cases are not seen by physicians. Reports concerning the appearance of the characteristic vesicular eruptions in the mouths of children were received during the 1914 outbreak. Although infection can doubtless occur by the contact of saliva or contents of the vesicles of infected cattle with abrasions of the skin, the commonly assigned mode of transmission to man is through unboiled milk, butter, cheese or other similar dairy products. In the recent outbreak the history of the cases is said to incriminate the milk supply. There is abundant evidence that the infectious agent can be destroyed with comparative ease by heat or the usual germicides. Physicians and health officials will be interested to learn, on the authority of a government publication,[1] that milk pasteurized at a temperature of 60 C. (140 F.) for twenty minutes is safe so far as infection by foot and mouth disease is concerned.

Fatal Poisoning from External Application of Resorcin.—C. Boeck of Christiania makes extensive use of mucilaginous mixtures containing resorcin in the treatment of lupus. He had never had any mishaps with it, even in a strength of 33 per cent. and more, until recently when he applied a 25 per cent. resorcin mixture to the greater part of the calf of a boy of 16. The lad had had lupus since the age of 3 and it had extended until the entire left leg and most of the left arm were involved. Half an hour after the application to the leg, made where the epithelium was intact throughout, the lad became restless and screamed with pain but soon quieted down. An hour and a half after the paste had been applied, he was found unconscious and cyanotic. Convulsions followed and the boy died nine hours after the application, without regaining consciousness. The formula for the paste was 15 parts resorcin; 15 parts talcum, and 30 parts gelatin base. Boeck has found three cases on record of similar toxic action from resorcin, but the two adults recovered. An infant, 11 days old, who had been treated with a 3 per cent. resorcinated petrolatum for pemphigus, died with symptoms of acute poisoning. The syndrome in all was the same as in Boeck's case. His report appears in the *Dermatologische Wochenschrift,* 1915, lx, 449.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

State Board Election.—At the annual meeting of the State Board of Health, held in Little Rock, May 7, Dr. Andrew L. Buckner, Dermott, was elected president and Dr. Charles W. Garrison, Little Rock, secretary.

Personal.—Dr. William S. Stewart, Pine Bluff, secretary of the State Board of Medical Examiners, is reported to be critically ill with disease of the kidney at St. Joseph's Infirmary, Hot Springs.——Dr. John C. Davis, Harrisburg, has succeeded Dr. George B. Fletcher, Little Rock, as a member of the staff of the State Hospital for Nervous Diseases, Little Rock.

State Board Changes.—The governor has appointed Drs. Wells F. Smith, Little Rock; and Julius A. Bogart, Forrest City, members of the State Board of Medical Examiners, and has reappointed Dr. F. T. Isbell, Horatio, to the board. The governor has appointed Dr. St. Cloud Cooper, Fort Smith, a member of the State Board of Nurse Examiners. ——J. B. Pond, Little Rock, has retired after twenty years of active service as president of the State Board of Pharmacists.

State Society Meeting.—The thirty-ninth annual meeting of the Arkansas Medical Society was held in Little Rock May 4 to 6, under the presidency of Dr. St. Cloud Cooper, Fort Smith. Dr. James C. Walles, Arkadelphia, was elected president; Dr. Clinton P. Meriwether, Little Rock, was reelected secretary, and Dr. William R. Bathurst, Little Rock, was reelected treasurer and editor of the *Journal of the Arkansas Medical Society.* Texarkana was selected as the place of meeting for 1916.

CALIFORNIA

Health Statistician Resigns.—Lewis Lee Loyle, deputy statistician of the State Board of Health, has resigned to take effect August 1.

Personal.—Dr. Stella M. Clarke, Los Angeles, has recovered after a long illness, and is on duty as house surgeon in the Hospital of the Good Samaritan, Los Angeles.——Dr. Shadworth O. Beasley, San Francisco, has been appointed assistant surgeon to the American Red Cross and has been assigned to duty in Belgrade, Serbia. He sailed from New York, May 1.——Dr. Ferdinand Stabel, Redding, who was attacked by a rabid dog, April 29, and started taking the Pasteur treatment in San Francisco two weeks later, is reported to be suffering from paralysis.——Dr. Jacob H. Parsegan, San Francisco, has returned after a visit of several months to Armenia.

Irregular Practitioners Convicted.—T. J. Pierce, San Francisco, is said to have plead guilty in the United States court to the charge of using the mails to advertise prohibited articles. He had conducted what is known as the Ramond Remedy Company in San Francisco. He was under investigation by the Board of Medical Examiners of the State of California and was convicted by that board, March 18, 1914. May 12, he was sentenced to imprisonment for six months in the county jail.——A jury in the United States court, San Francisco, is said to have brought in a verdict of guilty, May 7, in the case of Dr. Homer C. Edwards and Donald Harris, a student of medicine, on three counts of the joint indictment for fraudulent use of the mails. The jury recommended clemency in the case of Harris.

Appointments in Stanford Medical School.—The following appointments and promotions in the Stanford University Medical School are announced for the year 1915-1916: Dr. Charles Hervey Bailey, New York City, assistant professor of pathology; Dr. Henry Augustus Stephenson, Baltimore, assistant professor of obstetrics and gynecology; Dr. George de Forest Barnett, San Francisco, instructor in medicine; Dr. Jean Redman Oliver, San Francisco, instructor in pathology; Dr. George D. Lyman, San Francisco, clinical instructor in pediatrics; Dr. Shadworth Oldham Beasley, San Francisco, clinical instructor in obstetrics and gynecology; and Dr. Hans Barkan, San Francisco, clinical instructor in surgery, assigned to ophthalmology; Dr. Howard Y. McNaught, San Francisco, clinical instructor in surgery, assigned to otology, rhinology and laryngology.

First-Aid Demonstration at Exposition.—The third annual joint field meet of the United States Bureau of Mines, the American Mine Safety Association and the California Metal Producers' Association will be held at the Panama-Pacific Exposition, September 23 and 24. The joint meet either precedes or follows the annual meetings of a number of institutions allied to the mining interests, such as the American Institute of Mining Engineers, September 17 and 18; the International Engineering Congress, September 20 to 25; the American Mining Congress, September 20 to 22; the California State Mine Rescue and First Aid Contest, September 22, and the National Safety Conference, under the joint auspices of the National Safety Council and the California Industrial Accidents Commission, September 27 to 30. On September 23, on the athletic field of the exposition grounds, there will be a mine-rescue demonstration at 10 o'clock; at 2 o'clock in the afternoon there will be a first-aid demonstration, and at 4 o'clock a demonstration of the explosibility of coal dust. On September 24, at 10 o'clock, will be held a first-aid contest for interstate supremacy; at 2 in the afternoon a rescue contest for interstate supremacy; at 4 in the afternoon a rock-drilling contest, and at 8 o'clock in the evening there will be an award of prizes and souvenirs at the Convention Hall. Many well-known mining men and physicians have been assigned to the various committees to have charge of and to judge the field contests.

CONNECTICUT

Personal.—Dr. J. Francis Calef, Middletown, has been elected president of the New England Confederation of Examining Boards.——Frank J. Born, for nine years medical examiner for the Yale University Gymnasium and Athletic Association, has resigned to become dean of the normal school of physical education, Battle Creek, Mich.

State Society Election.—The one hundred and twenty-third annual meeting of the Connecticut State Medical Society was held in Hartford, May 19 and 20, and the following officers were elected: president, Dr. Max Mailhouse, New Haven; vice presidents, Drs. Charles B. Graves, New London, and Cushman A. Sears, New London; secretary, Dr. Marvin M. Scarbrough, New Haven (reelected); and treasurer, Dr. Joseph H. Townsend, New Haven (reelected). On the evening of May 20, the memorial dinner for the late Dr. Oliver C. Smith, Hartford, president of the society, was held at the Hartford Club. Dr. Edward T. Bradstreet, Meriden, made the memorial address.

FLORIDA

Sanatoriums Opened.—The new sanatorium, Jacksonville, was formally opened, May 18.——The new Sunnybrook Sanatorium on Miami Avenue, Miami, was opened for inspection, May 17.

State Association Meeting.—The Florida State Medical Association held its forty-second annual meeting in De Land, May 12 to 14, under the presidency of Dr. F. Clifton Moor, Tallahassee, and the following officers were elected: president, Dr. Robert H. McGinnis, Jacksonville; vice presidents, Drs. William R. Stephens, De Land; Mary Freeman, Perrine, and Joseph H. Coffee, Fort Meade. Arcadia was selected as the next place of meeting.

Health Bills Passed.—The State Board of Health bills, Nos. 135, 136 and 171, which had already been passed by the house, were adopted by the senate, May 7. Of these bills, the first provides for screens on service closets, fruit and vegetables exposed for sale, meats and other eatables. The second requires all school buildings to be provided with adequate facilities by water carriage of service closets, properly screened and fly proofed. The last bill provides for the State Board of Health Exhibit Train and places this exhibit at the disposal of the state for educational purposes.

Personal.—The garage of Dr. Robert L. Bryans, Pensacola, containing two automobiles, was destroyed by fire, May 16. ——A banquet was given by the Hillsboro County Medical Society at Tampa, April 22, in honor of Dr. Louis A. Bize, Tampa, who has retired from the practice of medicine to become president of the Citizens' Bank and Trust Company. Dr. Thomas Truelsen, Jr., acted as toastmaster.——A touring car containing Dr. Otis H. Johnson and his wife and two children, Jacksonville, plunged overboard from a ferry boat, May 9, and Dr. Johnson was the only one of the family saved.

ILLINOIS

Montgomery in Springfield.—Dr. Edward E. Montgomery, Philadelphia, was one of the guests of honor at the meeting of the Illinois State Medical Society and held a clinic in St. John's Hospital, Springfield, May 18.

Personal.—Dr. David S. Ray, mayor of Cuba, started May 19 on a trip to the Canal Zone.——Dr. James L. Reat, Tuscola, was thrown from his buggy, May 13, and painfully injured.——Dr. Jesse P. Simpson, Palmer, was painfully injured when an axle of his automobile broke near Palmer, May 13, overturning the car.

State Pays Claims for Stock.—The senate, on May 7, passed the bill appropriating about $1,000,000 to cover the state's half of the loss of cattle due to the foot and mouth epidemic. The bill was signed by the governor, May 12, and vouchers are now being mailed to each owner of cattle killed on account of the prevalence of the disease.

Hospital News.—The new amusement hall erected on the grounds of the Peoria State Hospital was formally dedicated, May 20. The new building is to be used for the recreation of patients, moving-picture shows, dances, etc.——Dr. Joseph B. Holmes, Macomb, announces that he will enlarge the Annex Hospital, will change its name to the Holmes Hospital and will devote his entire attention to the institution.——Plans are being prepared for the new building for the Maplewood Sanitarium, Jacksonville, to be erected this summer by Dr. Frank P. Norbury and Dr. Albert H. Dollear. The new building will accommodate fifty patients.

State Board Indorses Criticism.—In reply to the criticism made by the Federal authorities of the health laws of the state, the State Board of Health has issued a statement that in practically every detail it agrees with the criticism; that the report supports and corroborates the statement made by the board to the governor and its recommendation to the state efficiency and economy commission in September, 1914. The board agrees that reorganization is necessary; that medical registration functions be divorced from purely public health work and that all state agencies having to do with public health be brought together in one department.

Chicago

Fly Week.—By authorization of the mayor, the week of June 7 to 12 is proclaimed as Fly Week, and during this time every means will be used for the abolition of the fly pest. A special poster calling attention to the crusade has been prepared.

Prevention of Rabies.—The Chicago Medical Society, at its meeting May 26, devoted its entire meeting to a discussion of hydrophobia. The protective measures which the society demands are, that all homeless or ownerless dogs be destroyed; that each dog owner be compelled to register his animal, the penalty being death of the animal; that the city start a registration fee sufficient to pay for veterinary examination before issue of license, and that a year-round muzzling ordinance be passed and enforced.

INDIANA

The New Department of Tuberculosis.—Dr. John N. Hurty, Indianapolis, secretary of the Indiana State Board of Health, announced the appointment of Mr. Walter D. Thurber as deputy state health commissioner in charge of the new department of tuberculosis created by the last legislature. Mr. Thurber is now serving his third year as executive secretary of the Indiana Society for the Study and Prevention of Tuberculosis.

Personal.—Dr. John N. Taylor and wife, Crawfordsville, were seriously injured when their automobile crashed into a telephone pole near Warsaw.——Dr. John N. Hurty, health officer of Indiana, has been elected president of the Indianapolis Literary Club.—Dr. Clint C. Sourwine, Brazil, underwent a third operation for septicemia, May 15.——Dr. Boston H. B. Grayston, Huntington, was operated on for appendicitis at the Huntington Hospital, May 12.——Dr. William T. Ferguson, Fort Wayne, suffered amputation of his left leg below the knee on account of gangrene, May 12. ——Dr. Daniel S. Quickel, Anderson, while chopping wood, was struck in the eye by a piece of wood. The injury is said to be serious.——Dr. Edward P. Busse, Madison, formerly secretary of the Southwestern Indiana Insane Hospital, Madison, has opened a private hospital for the treatment of mental diseases at his old home in Evansville.——Dr. William A. Hollis, Hartford City, who has been ill with colon bacillus infection, is reported to be improving.

LOUISIANA

Freight Inspection Withdrawn.—Surg. Richard H. Creel, U. S. P. H. S., on duty at New Orleans, has ordered the discontinuance of the inspection of outgoing freight cars, which was inaugurated last summer during the active campaign against the bubonic plague.

Personal.—Dr. William T. O'Reilly has been elected president, and Dr. Sara T. Mayo, secretary, of the Sickles Board Fund.——The Italians of New Orleans gave a banquet in honor of Dr. Joseph A. Danna, May 8, in recognition of the work he has done in behalf of the poor of the city. At the banquet Chevalier Carlo di Papini, Italian vice consul, presented Dr. Danna with the decoration of Knight of the Crown of Italy.

Promotion of Mental Hygiene.—The first steps toward the organization of the Louisiana Society for the Promotion of Mental Hygiene were taken May 6, at a public conference in New Orleans, at which Clifford W. Beers explained the organization in other cities. Charles F. Fletchinger was elected temporary president and Dr. Maud Loeber, New Orleans, temporary secretary. The new organization is to be known as the Louisiana Society for Mental Hygiene.

Parish Society Condemns Nostrums.—The Vermilion Parish Medical Society, at its meeting May 20, adopted resolutions setting forth the evil of "patent medicines"; that these nostrums are pernicious and baneful; that benefits accruing from their sale are derived daily from the poor and unfortunate; that the society is in full sympathy with the efforts of the government in its attempts to expose the deception practiced in the manufacture, advertising and sale of the so-called remedies, such as wine of cardui, swamp root, syrup of figs, mothers' friend, vitalitas and the like, and is in hearty sympathy with the activities of the State Board of Health of Louisiana in its attack on these preparations and with its regulations requiring the printing of contents on the label; approving the campaign now in progress and pledging the earnest and active support of the society to their efforts toward the control and eventually the elimination of this evil.

MARYLAND

Psychopathic Building Opening.—The John Hubner Psychopathic Building at the Springfield State Hospital, Sykesville, will be formally opened on June 9. The speakers will be Governor Goldsborough and Drs. E. E. Southard of Boston, Hugh H. Young, Baltimore, president of the State Lunacy Commission, Henry M. Hurd and Edward N. Brush, Towson.

Polyglot Health Rules.—The health commissioner of Baltimore has had a pamphlet printed in English, Bohemian, Italian and Yiddish, of which ten thousand copies are to be distributed. This pamphlet teaches how to destroy flies and mosquitoes and tells tenants how to keep their premises in a clean and sanitary condition. The Poles of Baltimore have asked the commissioner of health to have this pamphlet translated into Polish.

Personal.—Dr. Arthur M. Shipley has been appointed acting dean of the medical school of the University of Maryland to fill the vacancy due to the death of Dr. R. Dorsey Coale.——Dr. Thomas S. Cullen, Baltimore, was operated on by Dr. John M. T. Finney, at Johns Hopkins Hospital, recently, for the removal of gallstones.——Dr. Alfred Whitehead, Baltimore, is under treatment at Johns Hopkins Hospital.——Dr. Richard H. Smith has been elected vice president of the board of directors of the Havre De Grace Hospital.——Assistant Surgeon-General Henry R. Carter, U. S. P. H. S., in charge of the United States Marine Hospital, Baltimore, who was operated on a short time ago, is reported to be convalescent.

Health Association for Colored People Organized.—The committee on public instruction of the Medical and Chirurgical Faculty of Maryland held a conference in Cambridge, May 17 to 19, under the auspices of the Dorchester County Sanitation League, and health officials in the campaign against the fly and mosquito and also to organize a colored county health association.——A colored health association which was recently organized in Annapolis, held its first public meeting, May 27, at which Dr. John S. Fulton, secretary of the State Board of Health; Mason Hawkins, principal of the colored high school of Baltimore, and president of the state colored association, Dr. Henry S. McCard, Baltimore; and Dr. Samuel J. Fort, secretary of the committee on public instruction, were the chief speakers. The subject for the evening was "The Relation of Tuberculosis and Typhoid Fever to the Colored Race."

MASSACHUSETTS

Industrial Accident Board.—The membership of the advisory committee of the Massachusetts Industrial Accident Board is as follows: Drs. Frederic J. Cotton, Boston; Francis W. Anthony, Haverhill; Samuel E. Fletcher, Chicopee; Samuel H. Calderwood, Roxbury; Francis D. Donoghue, Boston; Frank E. Allard, Boston; William H. Ruddick, Boston, and Walter P. Bowers, Clinton. Dr. Francis D. Donoghue has been selected by the board as its medical adviser.

Hospital Notes.—The establishment of a dispensary for tuberculosis has been delegated by the department of public health and charities at Lawrence, to the Antituberculosis League, Lawrence, and the dispensary will be open daily from 2 to 5, excepting on Wednesdays, when the hours are from 9 to 11 a. m., and also Thursday evenings, from 6:30 to 7:30. Dr. D. B. Sargent is medical adviser of the institution.——A series of receptions were held at the Lawrence General Hospital on May 18 to 20, when the entire plant, including the new children's ward and nurses' home, was opened for inspection.

State Society Meeting.—The one hundred and thirty-fourth annual meeting of the Massachusetts Medical Society will be held in Boston, June 8 and 9, under the presidency of Dr. Charles F. Withington, Boston. The annual dinner will be held at the Copley Plaza Hotel. On the first morning clinics and demonstrations will be held at the various hospitals. In the afternoon various sections will meet and in the evening the Shattuck lecture will be delivered by Dr. Joel E. Goldthwait, Boston, followed by the president's reception. On the second morning the informal exercises will take place. At noon the annual discourse will be delivered by Dr. Everett A. Bates, Springfield, whose topic will be "Some Perplexities in Modern Medicine," and in the afternoon there will be a joint meeting of sections with a symposium on Empyema. The annual dinner will be served on Wednesday evening at 7 o'clock.

MISSOURI

Missouri Declares Quarantine.—A provisional quarantine against all live stock from the states of Arizona, California, Nevada, Oregon, Utah and Washington was declared by the Missouri State Board of Agriculture, May 21.

Expedition to Honduras.—The St. Louis University will send an expedition to British Honduras this summer for the study of biology and preventive medicine with the object of establishing a permanent station for work in these specialties.

Dinner to Dr. Loeb.—A testimonial dinner was tendered to Dr. Leo Loeb at the University Club, St. Louis, May 25, by members of the medical profession of St. Louis, the scientific faculties of Washington University and St. Louis University and members of the Biological Society of St. Louis. Among the speakers were Profs. Robert J. Terry of Washington University, Ralph L. Thompson of St. Louis University, Augustus G. Pohlman and Walter E. Garrey; Dr. George Gellhorn and Messrs. Edwin Mallinckrodt, Jr., and Regis Chauvenet.

New Hospitals.—Dr. Halsey M. Lyle announces the opening of a hospital in Kansas City for the treatment of skin diseases and cancer.——Dr. Walter E. Cary has opened a hospital in Kansas City for the treatment of nervous and mental diseases.——The new Muncipal Tuberculosis Hospital, Kansas City, at the Leeds Farm, is approaching completion and will be ready to receive patients in about sixty days. The building has cost $150,000 and will accommodate about 150 patients.——An eye, ear, nose and throat clinic has been established by Father Dempsey at his day nursery, 1209 N. Sixth Street, St. Louis. The clinic is open on Saturdays and Mondays from 3 to 5 p. m.

Personal.—Dr. Carlos C. English, resident physician at the State Sanatorium for Tuberculosis, Mount Vernon, has been appointed superintendent succeeding Dr. Bondurant Hughes, resigned.——Dr. James Stewart, superintendent of hygiene of the public schools of St. Louis, has recovered after a surgical operation.——Dr. Horace T. Price has been appointed medical examiner of the Efficiency Board of St. Louis.——Dr. Hasbrouck De Lamater, until recently assistant health commissioner of Kansas City, has entered private practice.——Dr. Max C. Starkloff has been reappointed health commissioner of St. Louis.——Dr. Moyer S. Fleisher, who has been assistant in the department of pathology of the St. Louis Barnard Free Skin and Cancer Hospital, has been appointed assistant professor of bacteriology in the St. Louis University School of Medicine.

NEW YORK

Tribute to Anatomist.—The 1915 *Skull*, the annual of the student body of Albany Medical College, is dedicated to Dr. Joseph Davis Craig, for thirty years professor of anatomy in the college.

Addition to Hospital.—The State of New York has recently commenced the erection of a $10,000 addition to the present General Hospital erected at a cost of $15,000 at the State Agricultural and Industrial School, Industry. This addition is required to enable the school physician properly to care for the health and correction of physical defects in the 700 or more inmates of the institution.

Health Department and Occupational Diseases.—The Health Department has organized an Occupational Clinic at 49 Lafayette Street and in connection with the work of the clinic has prepared a clinical history card, which is of interest and may help to indicate lines along which investigation may yield clinical results. It is the belief of those interested in this subject that if some of the data included on this card were asked in the course of clinical examinations conducted in dispensaries, hospitals and in private practice, a number of obscure diseases whose causes lie in the occupation of the individual, would be brought to light. A factory survey card which a medical inspector fills out prior to the examination of a given group of working people in any particular factory is also used in connection with the data of the clinical history card of the Occupational Clinic, and together they give a comprehensive picture to the examiners at the Occupational Clinic of the various factors which operate to produce occupational diseases or to lower health.

New York City

Physician Leaves Large Estate.—The late Dr. Everett Herrick, who died April 1, 1914, left an estate of $1,335,458.

Sails to Head Field Hospital.—Dr. Berkeley Sherwood-Dunn, physician and banker, sailed May 15 for France, where he will take command of a field hospital.

Beriberi Near New York.—A wireless message received May 26 by Health Officer O'Connell, states that the British steamer *Dewa* from Cienfuegos, Cuba, for New York, has twenty-five cases of beriberi among its crew of forty men, and that eight men have died from the disease since the vessel sailed.

The Arbuckle Memorial.—The north wing of the Long Island College Hospital, presented to the hospital in memory of John Arbuckle by his two sisters, was opened on May 24. It will house 171 male patients, and contains, besides the wards and private rooms, a clinical laboratory for 45 medical students and three research laboratories for the use of clinical research workers.

Dinner to Dr. Fuhs.—A farewell dinner was given to Dr. Jacob Fuhs by the visiting and assistant visiting staffs and the Alumni Association of St. Catherine's Hospital, Brooklyn. The occasion of the dinner was the resignation of Dr. Fuhs, after forty years of service as visiting physician to the hospital. Dr. Mathias Figueira presided as chairman. A set of resolutions laudatory of Dr. Fuhs was adopted and a copy bound in seal leather was presented to him.

Port Health Officer Opposes Federal Jurisdiction.—Dr. Joseph J. O'Connell, health officer of the port of New York, opposes the suggestion that his department be placed under federal control for the sake of economy. Dr. O'Connell claims that this change will impose a greater financial burden on the state than that entailed under the present plan of state control. At present the state pays 20 per cent. of the maintenance cost of this department. Under federal control, he claims, this amount would be increased to 27, or even 30 per cent.

New Diphtheria Hospital.—Bids for the construction of a new diphtheria hospital, Brooklyn, were advertised, May 22. The new hospital will be under the direction of the department of health and will be one of a group of buildings on Kingston Avenue, devoted to the treatment of communicable diseases. The building will be three stories in height, the central portion, 50 by 44, with a wing on either side, 58 by 28. The building will be fireproof throughout and will accommodate eighty patients under normal conditions. It will cost about $100,000.

Opportunity to Study Occupational Diseases.—The health department announces that it desires to secure the assistance of competent clinical workers for its occupational clinic. In the budget a request will be made for a number of positions for clinic physicians at $300 per annum. The hours of work will be two and one-half hours three times a week. This will offer an unusual opportunity to do research work in the study of occupational diseases which, it is predicted, will in a short time assume a most important rôle in preventive medicine.

Survey of Disease Clinics.—The social hygiene division of the Charities and Correction Conference, at a meeting, May 17, presented the following report: Of twenty-seven venereal disease clinics in New York City, only seven have complied with the recommendations of the Associated Out-Patients' Clinics. The insanitary condition of the clinics must be improved and common standards for discharging patients must be followed. The remedies proposed include wider publicity of recommendations and better cooperation between dispensary authorities and clinic chiefs. Knowledge of conditions existing and the results accomplished is essential to the intelligent direction of a clinic. In the four venereal disease clinics studied this information had never been recorded. It was obtainable, though with great difficulty, in only two. Three-fourths of the patients "ceased treatment unimproved." One-half of the patients made too few visits to hope to be cured. Much of the time and money expended on these was wasted. The remedies proposed are: (1) Determine how much time and money is wasted; (2) get the patients to come back.

NORTH CAROLINA

State Society Meeting.—The Medical Society of the State of North Carolina will hold its annual meeting in Greensboro, June 14 to 17. In connection with this meeting will be held the annual meeting of the State Health Officers' Association.

Antityphoid Campaign.—Wake, Northampton and Edgecomb counties have decided to hold antityphoid immunization campaigns during the summer and have made appropriations for this work. In these campaigns the counties will provide for the local expenses of the dispensaries and the State Board of Health will furnish the antityphoid vaccine and literature, and will direct and assist at various dispensaries.

Convict Camps.—Dr. Watson S. Rankin, Raleigh, secretary of the State Board of Health, has made a report on the condition of the convict camps in Nash County. As the result of his investigation, he recommends that the State Board of Health be directed to make an inspection of the convict camps of ten counties in North Carolina, with the object of improving the sanitary condition in these camps.

Full Appropriation for Hospital.—After a conference between the governor, council of the state, legislative finance committee and directors of the Webster Hospital for the Insane, Morgantown, it was decided that the hospital is to have the full appropriation of $200,000 for maintenance, without regard to the apparently mythical accumulated balance of $76,000 which the legislative finance committee declared the institution to have.

Hospital News.—At a meeting of the Negro Medical and Pharmaceutical Association of Guilford County, held at High Point, May 10, a resolution was adopted that the association establish a hospital for the care of colored people of Guilford County, to be located at Greensboro.——The Charlotte Sanatorium Company has been incorporated by Dr. Robert L. Gibbon, Charlotte, and others, with a capital stock of $125,000, to run and operate the Charlotte Sanatorium.

Decision of Supreme Court on Practicing Without License by Nondrug-Giving Physician.—An individual calling himself Dr. Siler was engaged in Greensboro, N. C., in the practice of "chiropractic and suggestotherapy." He was indicted for practicing without license, and on a special verdict the trial judge found him not guilty, and the ruling of the lower court was appealed to the supreme court for final action. Chief Justice Clark, in the decision, held that the act of 1913 amending the act of 1907 requires that all nondrug-giving physicians shall be licensed by the nondrug board before engaging in the practice of their profession. In the case in question it appeared that "Dr. Siler" was not, according to his contention, practicing osteopathy, but was engaged in the "practice of chiropractic and suggestotherapy" and received compensation therefor. Chiropractic, it was submitted to the court, "is a system of treating human diseases without the use of drugs by mental suggestion," and it was admitted that the defendant had not been licensed by the osteopathic board. The defense contended that the act of 1907, as amended by that of 1913, does not require nondrug-giving practitioners, other than osteopaths, to pass examinations or take out license, and that if it did, such requirement would be unconstitutional. The court opinion, after reviewing the law applicable, says the act of 1913 simply extends the act of 1907 to require "the examination and licensing of all other nondrug-giving practitioners, by whatever name known," and makes those violating this statute "guilty of a misdemeanor to the same extent as those who practiced as osteopaths without complying with the requirements of the act of 1907." The chief justice ruled that the law of 1907, as amended in 1913, was for the protection of the public by requiring all nondrug-giving physicians to be regularly licensed, and that on the special verdict the court should have found the defendant guilty. This decision sets at rest a question that has been considered at different times in the state, at least by implication, and definitely adjudges the province of the State Board of Medical Examiners to be to examine and license physicians who give drugs, while it positively rules that all nondrug-giving physicians, of whatsoever name, shall be examined and licensed by the State Board of Examiners of Osteopathy.

PENNSYLVANIA

Personal.—Dr. Calvin L. Johnstonbaugh, Bethlehem, has been reappointed a member of the Board of Medical Education and Licensure.——Dr. Daniel R. McCormick, Lancaster, suffered a cerebral hemorrhage, May 21.——Dr. P. Joseph Faughnan, Locust Gap, was operated on at the Shamokin Hospital, recently, for strangulated hernia.——Dr. James Burns Amberson, Waynesboro, was given a silver loving-cup by the members of the Waynesboro Academy of Medicine, May 15, in honor of his seventieth birthday.——Dr. William F. Muhlenberg of Reading has been chosen president by the executive committee of the Pennsylvania German Society.——Dr. Edwin S. Dorworth, Bellefonte, who recently completed fifty years of practice of medicine in Center County, and also celebrated his eighty-first birthday anniversary, was accorded an informal reception and dinner by the Center County Medical Society.

Philadelphia

Club Reception.—The Medical Club of Philadelphia will give a reception in honor of Rear Admiral William S. Benson, U. S. Navy, at the Bellevue Stratford, June 11.

Graduating Exercises.—The sixty-third annual commencement exercises of the Woman's Medical College of Pennsylvania were held in the Garrick Theater, June 2, at 11 o'clock. The address was delivered by Dr. Richard C. Cabot, Boston. In the evening, a reception was given by the corporators and faculty in honor of the graduating class.——The sixty-third annual commencement of Jefferson Medical College will be held at the Academy of Music, June 5, and Dr. Victor C. Vaughan of the University of Michigan medical faculty will deliver the valedictory, "A Doctor's Ideals."

In Spite of Difficulties.—James Keith of Shafferstown, Pa., a student at Jefferson Medical College, who was taken to the Jefferson Hospital in April, 1914, with his back broken as a result of a fall from the window of a fraternity house, and who has since had one leg amputated, has successfully passed his final senior examinations, and will receive the medical diploma.

Appeal for Free Bed.—The Alumni Association of Jefferson Medical College makes another appeal for contributions to the endowment fund for the establishment of a free bed in Jefferson Hospital for the care of poor graduates. At the present time about $1,700 has been contributed. The past year's experience has taught that many men are in need and a room of this kind is a necessity.

Personal.—Dr. R. Tait McKenzie, director of the department of physical education at the University of Pennsylvania, sailed, May 29, for London, where he is to aid in "hardening up" British recruits. He will take charge of the new physical department established by the British government, will be posted outside of London with a staff of experts, and will look after the physical conditions of the men who are preparing to go to the front. It is reported that Dr. McKenzie has been granted a year's leave of absence from the university.——Howard B. Lewis, Ph.D., instructor in physiologic chemistry of the University of Pennsylvania, has been appointed to an associate professorship by the trustees of the University of Illinois.——Dr. Barton K. Thomas was operated on for tumor of the abdominal wall at Jefferson Hospital, May 17, and is reported to be doing well.——Dr. Joseph Pasceri has been called to the colors by the Italian consul.

Against Insanitary Barbers.—A campaign of education of the public against insanitary barbers has been started in Philadelphia. Bulletins on the subject were sent out, May 24, by the Department of Public Health. The public is warned not to employ barbers suffering from infectious diseases, and is told that boils, erysipelas, ringworm, barber's itch, conjunctivitis and virulent ophthalmia may be transmitted by uncleanliness. For the barber's observance, the department urges rules which call for the sterilization of hairbrushes and combs by formaldehyd, and the sterilization of razors, shears, clippers and tweezers by immersion in boiling water or wiping with cotton moistened in acetone-alcohol or hydrogen peroxid. Individual towels should be used instead of powder puffs, sponges and finger bowls. The common cosmetic stick should be avoided. Bleeding should be stopped by applying cotton which has been dipped into a solution of epinephrin chlorid to the wound.

SOUTH DAKOTA

State Society Meeting.—The thirty-fourth annual meeting of the South Dakota State Medical Association was held in Sioux Falls, May 18 to 20, under the presidency of Dr. Fred Treon, Chamberlain, whose presidential address was on "Some Practical Considerations in the Diagnosis of Abdominal Conditions." The following officers were elected: president, Dr. James B. Vaughn, Castlewood; vice-presidents, Drs. Francis M. Crain, Redfield, and Herman J. G. Koobs, Scotland, the secretary holding over until the next meeting. Dr. Leslie G. Hill, Watertown, was selected as delegate to the American Medical Association. Aberdeen was selected as the place of meeting for 1916.

WEST VIRGINIA

Health Survey Desired.—The Clarksburg Board of Trade has requested the Surgeon-General of the United States Public Health Service to make a field survey on health and sanitation in Harrison County.

Personal.—The residence of Dr. Willis St. Michael, Hendricks, was destroyed by fire to the extent of $1,500, May 14.——Dr. Sylvanus L. S. Spragg, Wheeling, who has been ill with pneumonia, is reported to be convalescent.——Dr. Will S. Keever, Parkersburg, was injured in a railway accident in Baltimore, recently.

Higher Standard Adopted.—The new announcement of the West Virginia University, just received, states that on and after Sept. 1, 1917, two years of collegiate work (sixty-four credit hours), including courses in physics, chemistry, biology and French or German, will be required for admission to the medical school.

State Association Meets in Huntington.—The forty-eighth annual meeting of the West Virginia State Medical Association was held in Huntington, May 12 to 14, under the presidency of Dr. Henry P. Linsz, Wheeling, and the following officers were elected: president, Dr. Arthur P. Butt, Davis; vice presidents, Drs. Albert S. Bosworth, Elkins; George C. Schoolfield, Charleston, and Sidney B. Lawson, Logan; secretary, Dr. J. Howard Anderson, Marytown (reelected); treasurer, Dr. Hugh G. Nicholson, Charleston (reelected); editor of the association magazine, Dr. James R. Bloss, Huntington; and councilors, first district, Drs. James W. McDonald and Henry R. Johnson, both of Fairmont; second district, Dr. Theodore K. Oates, Martinsburg; Hoddie W. Daniels, Elkins; third district, Drs. Chester R. Ogden, Clarksburg, and Morgan T. Morrison, Sutton; fourth district, Drs. Joseph E. Rader, Huntington, and George D. Jeffers, Parkersburg; fifth district, Dr. Wade H. St. Clair, Bluefield, and Elbert F. Peters, Maybeury; and sixth district, Dr. Peter A. Haley, Charleston, and Benjamin B. Wheeler, McKendree. Dr. John L. Dickey, Wheeling, was elected delegate to the American Medical Association, and Dr. Frank LeMoyne Hupp, Wheeling, alternate. Wheeling was selected as the next place of meeting.

CANADA

Gift to Dalhousie.—Investments to the value of $30,000 have been given to Dalhousie University, Halifax, N. S., to go toward the endowment of a chair of anatomy, and announcement has been made that in the near future, the sum will be doubled.

New Quarters for Medical School.—The Faculty of Medicine of Dalhousie University, Halifax, is to be moved this summer into the large brick and stone building heretofore occupied by the Faculty of Arts and Sciences, and the latter department will move into new buildings which have just been completed.

University of Toronto Base Hospital Arrives in England.—The University of Toronto Base Hospital, under command of Lieut.-Col. James A. Roberts, arrived at Plymouth safely May 27. It is understood that it will proceed to France at once and most likely be located at Dieppe. All the members of the staff were well.

Care of Feebleminded in Ontario.—Mr. Justice Osler, Toronto, and Dr. Helen MacMurchy, Toronto, have been appointed chairman and secretary, respectively, of the newly appointed committee in Toronto, to consider the care of the feebleminded in that city. Dr. MacMurchy represents the Ontario government, and Dr. Charles J. C. O. Hastings, M.O.H., Toronto, has been appointed on the committee to represent the city council.

Western University Convocation.—Convocation was held at the Western University, London, Ont., May 28. Dr. Hugh A. MacCallum, on behalf of the board of governors, announced that Dr. Hibbert W. Hill would return from Minnesota to take up again his office as superintendent of the Hygienic Institute, for whom a worthy successor had been sought but not found. Dr. Hill will remain with the Institute until it has demonstrated its usefulness to western Ontario. Four new professors will be secured for the next college year.

Ontario Government to Donate Hospital for War.—The Ontario government has decided to establish and maintain in England a hospital of 1,000 beds for the treatment of Canadian wounded. The idea is to have ten cottages with 100 beds in each, the cost of construction of which will be about $100,000. The government will also provide immediately six motor ambulances. Sir Adam Beck, who has just returned from England, laid before the government the great need for hospital accommodation. The government has been in communication with Col. George A. S. Ryerson, Toronto, president of the Canadian Red Cross Society. Lieut.-Col. Arthur E. Ross, M.D., M.P.P., Kingston, who is at the front, has advised the government that these ambulances are urgently needed.

Ontario Medical Association.—The annual meetings of the Ontario Medical Association and the Association of Health Officers of Ontario was held in Peterboro, May 25-27. Dr. D. J. Gibbs, Wishart, Toronto, delivered the presidential address, speaking on the part the medical profession had done in Ontario for the war, and instancing the University of Toronto Base Hospital, Queen's Base Hospital, Peterboro Base Hospital of 200 beds, which have been accepted, and the offer of Lambton County for a similar hospital. The main part of his address dealt with specialism in medicine. Dr. Francis J. Shepherd, Montreal, *delivered the address in* surgery. A resolution was adopted calling on medical men to educate the public in the matter of cancer. Another was adopted pledging members of the profession to preserve the practices of those who had gone abroad to serve their country until their return. The following officers were elected: president, Dr. Harry B. Anderson, Toronto; vice presidents, Drs. George S. Cameron, Peterboro; Edward B. Oliver, Fort William; William Colbeck, Welland; Arthur T. Emmerson, Goderich; general secretary, Dr. F. Arnold Clarkson, Toronto; assistant secretary, Dr. Frederick C. Harrison, Toronto, and treasurer, Dr. Jabez H. Elliott, Toronto.

GENERAL

Santa Fe Surgeons to Meet in San Francisco.—The Santa Fe Medical and Surgical Society announces that it will hold its annual meeting in San Francisco, June 20 to 25.

Anesthetists to Meet.—The third annual meeting of the American Association of Anesthetists will be held in San Francisco, June 21, under the presidency of Dr. Charles K. Teter, Cleveland.

School Hygiene to Meet in San Francisco.—The eighth congress of the American School Hygiene Association will be held in the Civic Auditorium, San Francisco, June 25 and 26, under the presidency of Dr. Henry M. Bracken, St. Paul.

Fraternity Meeting Announced.—The annual convention of the Grand Chapter of the Omega Upsilon Phi will be held in San Francisco, June 25 to 26. Further information regarding this meeting may be obtained from Dr. Calvin A. Walker, 292 Third Street, San Francisco.

Pediatrists Elect Officers.—At the twenty-seventh annual meeting of the American Pediatric Society held at Lakewood, N. J., May 25 to 27, the following officers were elected: president, Dr. Rowland G. Freeman, New York City; vice president, Dr. John C. Gittings, Philadelphia; secretary, Dr. Samuel S. Adams, Washington, D. C. (reelected); treasurer, Dr. Charles Hunter Dunn, Boston, and editor and recorder, Dr. Linnalus E. LaFetra, New York City.

Red Cross Appeals for Mexicans.—The American Red Cross has made an appeal to the American people and has sent a telegram to the governor of each state and a letter to each State Board of Health, conveying the information that there are a large number of unfortunate people in Mexico facing death by starvation, and the president of the United States and the American Red Cross make an appeal for money and food supplies. Gifts of corn, beans, rice and flour will be accepted at any point in the United States and forwarded by the Red Cross to Mexico through the most practicable routes to reach the people in distress. Money may be sent to local Red Cross treasurers or to Red Cross headquarters at Washington. Before donated supplies are sent from any point instructions from Washington will be furnished for routing. The most practicable gateways into Mexico at the present time and under present conditions are Vera Cruz (via Galveston), Brownsville, Laredo, Eagle Pass and El Paso, Texas; and Nogales, Ariz.

Bequests and Donations.—The following bequests and donations have recently been announced:

University and Episcopal hospitals, Philadelphia, each $25,000, contingent bequests, and a direct bequest of $1,000 to the Home for Crippled Children, by the will of Josephine Lewis.

Johns Hopkins University, bonds to the value of $100,000, by an anonymous donor, subject to a *life interest*.

Medical and Chirurgical Faculty of Maryland, sixty shares of stock in the National Bank of Elkton, Md., by the will of the late Dr. Charles M. Ellis, Elkton.

Boehne Tuberculosis Camp near Evansville, an additional donation of $12,000, by Mr. John W. Boehne.

Daviess County Hospital Association, Washington, Ind., property valued at $8,000, by the will of Mrs. Matilda L. Wilson.

St. Francis' Hospital, Hartford, Conn., nearly $5,000, the proceeds of a *play given by* local talent.

New York Academy of Medicine, $50,000, one half for the library fund and one half for the permanent fund; New York Skin and Cancer Hospital, $25,000, and Society for the Relief of the Ruptured and Crippled, and Association for Improving the Condition of the Poor, each $10,000 by the will of Dr. Everett Herrick, New York City.

General hospitals of New York City, $58,355; special hospitals, $18,931; hospitals for women and children, $18,749; hospitals for incurables, $13,963; making it altogether $110,000, distributed among the Associated hospitals by the Hospital Saturday and Sunday Association.

White Plains (N. Y.) Hospital; St. Luke's Hospital, New York City; German Hospital and Dispensary, New York, and White Plains Nurses' Association, each $1,000 by the will of Henry Ungrish, Jr.

Dr. William G. Choate, Hot Springs, Ark., $57,000 for the purpose of establishing at that place a hospital for the poor by the will of *Patrick Fenton, Knoxville, Tenn.*

Pittsfield (Mass.) Antituberculosis Association, $15,000, and House of Mercy Hospital, Pittsfield, $5,000 by the will of Dr. Frederick S. Coolidge.

New York Homeopathic and Flower Hospital, $1,000 for the students endowment fund and $5,000 for the establishment of a bed, by the will of Miss Thena M. Mills.

WAR NOTES

Roumanian Decorations for Behring and Ehrlich.—The *Klinisch-therapeutische Wochenschrift* of May 17 states that the Royal Roumanian cross of the first class for Sanitätsverdienst—which may be translated "for merit in sanitary service"—has been conferred on von Behring and Ehrlich.

Typhus in Turkey.—Dr. Stapleton, writing from Erzeroum, asks urgently for equipment for 200 beds. Typhus fever is reported to be raging in Turkey and is present in epidemic form in Sivas.——In Konia Dr. Dodd has removed its patients to a special building about a mile from the city proper, and has thus been able to prevent the spread of the disease in the hospital.

Red Cross Reenforcements for Austria.—The American Red Cross personnel, which started for Austria, via Genoa, early in May, left Genoa, May 29, for Vienna, by way of Switzerland. The party consisted of Dr. Walpole C. Brewer, Atlanta, Ga., and seventeen nurses. At Vienna the nurses will be divided between the Red Cross hospitals at Vienna and Budapest.

Only Trained Nurses Accepted for German Base Hospitals.—According to a recent regulation of the war department in Germany, only trained nurses are to be accepted for the examinations or take out license, and that if it did, such requirement would be unconstitutional. The court opinion, after reviewing the law applicable, says the act of 1913 simply extends the act of 1907 to require "the examination and licensing of all other nondrug-giving practitioners, by whatever name known," and makes those violating this statute "guilty of a misdemeanor to the same extent as those who practiced as osteopaths without complying with the requirements of the act of 1907." The chief justice ruled that the law of 1907, as amended in 1913, was for the protection of the public by requiring all nondrug-giving physicians to be regularly licensed, and that on the special verdict the court should have found the defendant guilty. This decision sets at rest a question that has been considered at different times in the state, at least by implication, and definitely adjudges the province of the State Board of Medical Examiners to be to examine and license physicians who give drugs, while it positively rules that all nondrug-giving physicians, of whatsoever name, shall be examined and licensed by the State Board of Examiners of Osteopathy.

PENNSYLVANIA

Personal.—Dr. Calvin L. Johnstonbaugh, Bethlehem, has been reappointed a member of the Board of Medical Education and Licensure.——Dr. Daniel R. McCormick, Lancaster, suffered a cerebral hemorrhage, May 21.——Dr. P. Joseph Faughnan, Locust Gap, was operated on at the Shamokin Hospital, recently, for strangulated hernia.——Dr. James Burns Amberson, Waynesboro, was given a silver loving-cup by the members of the Waynesboro Academy of Medicine, May 15, in honor of his seventieth birthday.——Dr. William F. Muhlenberg of Reading has been chosen president by the executive committee of the Pennsylvania German Society.——Dr. Edwin S. Dorworth, Bellefonte, who recently completed fifty years of practice of medicine in Center County, and also celebrated his eighty-first birthday anniversary, was accorded an informal reception and dinner by the Center County Medical Society.

Philadelphia

Club Reception.—The Medical Club of Philadelphia will give a reception in honor of Rear Admiral William S. Benson, U. S. Navy, at the Bellevue Stratford, June 11.

Graduating Exercises.—The sixty-third annual commencement exercises of the Woman's Medical College of Pennsylvania were held in the Garrick Theater, June 2, at 11 o'clock. The address was delivered by Dr. Richard C. Cabot, Boston. In the evening, a reception was given by the corporators and faculty in honor of the graduating class.——The sixty-third annual commencement of Jefferson Medical College will be held at the Academy of Music, June 5, and Dr. Victor C. Vaughan of the University of Michigan medical faculty will deliver the valedictory, "A Doctor's Ideals."

In Spite of Difficulties.—James Keith of Shafferstown, Pa., a student at Jefferson Medical College, who was taken to the Jefferson Hospital in April, 1914, with his back broken as a result of a fall from the window of a fraternity house, and who has since had one leg amputated, has successfully passed his final senior examinations, and will receive the medical diploma.

Appeal for Free Bed.—The Alumni Association of Jefferson Medical College makes another appeal for contributions to the endowment fund for the establishment of a free bed in Jefferson Hospital for the care of poor graduates. At the present time about $1,700 has been contributed. The past year's experience has taught that many men are in need and a room of this kind is a necessity.

Emmerson, Goderich; general secretary, Dr. F. Arnold Clarkson, Toronto; assistant secretary, Dr. Frederick C. Harrison, Toronto, and treasurer, Dr. Jabez H. Elliott, Toronto.

GENERAL

Santa Fe Surgeons to Meet in San Francisco.—The Santa Fe Medical and Surgical Society announces that it will hold its annual meeting in San Francisco, June 20 to 25.

Anesthetists to Meet.—The third annual meeting of the American Association of Anesthetists will be held in San Francisco, June 21, under the presidency of Dr. Charles K. Teter, Cleveland.

School Hygiene to Meet in San Francisco.—The eighth congress of the American School Hygiene Association will be held in the Civic Auditorium, San Francisco, June 25 and 26, under the presidency of Dr. Henry M. Bracken, St. Paul.

Fraternity Meeting Announced.—The annual convention of the Grand Chapter of the Omega Upsilon Phi will be held in San Francisco, June 25 to 26. Further information regarding this meeting may be obtained from Dr. Calvin A. Walker, 292 Third Street, San Francisco.

Pediatrists Elect Officers.—At the twenty-seventh annual meeting of the American Pediatric Society held at Lakewood, N. J., May 25 to 27, the following officers were elected: *president, Dr. Rowland G. Freeman, New York City;* vice president, Dr. John C. Gittings, Philadelphia; secretary, Dr. Samuel S. Adams, Washington, D. C. (reelected); treasurer, Dr. Charles Hunter Dunn, Boston, and editor and recorder, Dr. Linnalus E. LaFetra, New York City.

Red Cross Appeals for Mexicans.—The American Red Cross has made an appeal to the American people and has sent a telegram to the governor of each state and a letter to each State Board of Health, conveying the information that there are a large number of unfortunate people in Mexico facing death by starvation, and the president of the United States and the American Red Cross make an appeal for money and food supplies. Gifts of corn, beans, rice and flour will be accepted at any point in the United States and forwarded by the Red Cross to Mexico through the most practicable routes to reach the people in distress. Money may be sent to local Red Cross treasurers or to Red Cross headquarters at Washington. Before donated supplies are sent from any point instructions from Washington will be furnished for routing. The most practicable gateways into Mexico at the present time and under present conditions are Vera Cruz (via Galveston), Brownsville, Laredo, Eagle Pass and El Paso, Texas; and Nogales, Ariz.

Bequests and Donations.—The following bequests and donations have recently been announced:

University and Episcopal hospitals, Philadelphia, each $25,000, contingent bequests, and a direct bequest of $1,000 to the Home for Crippled Children, by the will of Josephine Lewis.

Johns Hopkins University, bonds to the value of $100,000, by an anonymous donor, subject to a life interest.

Medical and Chirurgical Faculty of Maryland, sixty shares of stock in the National Bank of Elkton, Md., by the will of the late Dr. Charles M. Ellis, Elkton.

Boehne Tuberculosis Camp near Evansville, an additional donation of $12,000, by Mr. John W. Boehne.

Daviess County Hospital Association, Washington, Ind., property valued at $8,000, by the will of Mrs. Matilda L. Wilson.

St. Francis' Hospital, Hartford, Conn., nearly $5,000, the proceeds of a play given by local talent.

New York Academy of Medicine, $50,000, one half for the library fund and one half for the permanent fund; New York Skin and Cancer Hospital, $25,000, and Society for the Relief of the Ruptured and Crippled, and Association for Improving the Condition of the Poor, each *$10,000 by the will of Dr. Everett Herrick, New York City.*

General hospitals of New York City, $58,355; special hospitals, $18,931; hospitals for women and children, $18,749; hospitals for incurables, $13,963; making it altogether $110,000, distributed among the Associated hospitals by the Hospital Saturday and Sunday Association.

White Plains (N. Y.) Hospital; St. Luke's Hospital, New York City; German Hospital and Dispensary, New York, and White Plains Nurses' Association, each $1,000 by the will of Henry Ungrish, Jr.

Dr. William G. Choate, Hot Springs, Ark., $57,000 for the purpose of establishing at that place a hospital for the poor by the will of Patrick Fenton, Knoxville, Tenn.

Pittsfield (Mass.) Antituberculosis Association, $15,000, and House of Mercy Hospital, Pittsfield, $5,000 by the will of Dr. Frederick S. Coolidge.

New York Homeopathic and Flower Hospital, $1,000 for the students endowment fund and $5,000 for the establishment of a bed, by the will of Miss Thena M. Mills.

WAR NOTES

Roumanian Decorations for Behring and Ehrlich.—The *Klinisch-therapeutische Wochenschrift* of May 17 states that the Royal Roumanian cross of the first class for Sanitätsverdienst—which may be translated "for merit in sanitary service"—has been conferred on von Behring and Ehrlich.

Typhus in Turkey.—Dr. Stapleton, writing from Erzeroum, asks urgently for equipment for 200 beds. Typhus fever is reported to be raging in Turkey and is present in epidemic form in Sivas.——In Konia Dr. Dodd has removed its patients to a special building about a mile from the city proper, and has thus been able to prevent the spread of the disease in the hospital.

Red Cross Reenforcements for Austria.—The American Red Cross personnel, which started for Austria, via Genoa, early in May, left Genoa, May 29, for Vienna, by way of Switzerland. The party consisted of Dr. Walpole C. Brewer, Atlanta, Ga., and seventeen nurses. At Vienna the nurses will be divided between the Red Cross hospitals at Vienna and Budapest.

Only Trained Nurses Accepted for German Base Hospitals.—According to a recent regulation of the war department in Germany, only trained nurses are to be accepted for the

Reservelazaretten and volunteer nurses only when they belong to some recognized organization. Under exceptional circumstances the physician in chief is empowered to retain especially efficient nurses.

Russian Women Medical Students Called on for Professional Services in the Field Hospitals.—A German exchange mentions that in Russia the minister for public instruction has notified the medical colleges which have women in their classes that women students who have studied for six semesters or more are liable to be called on for service in the hospitals at the front.

Woman Appointed Army Surgeon.—The wife of the orthopedic surgeon, Professor Helbing of Berlin, is a registered physician and specializes also in orthopedic surgery. She has been for several months at work among the wounded soldiers, and recently she has been given an official position. As our German exchanges remark, Frau Grete Schüler-Helbing is thus the first German *Militärärztin.*

War Notes from The Journal for the Belligerent Countries.—The *Policlinico* of Rome, Italy, publishes a number of "war notes" regarding happenings in the medical world across the border in Austria and Germany, but adds that the information was all derived from THE JOURNAL. It also prints news about its neighbors to the east in Greece and numbers of items of news from France, all taken from THE JOURNAL.

Red Cross Work in Turkey.—The Constantinople Chapter of the American Red Cross has taken charge of the British and French hospitals in that city. In these two hospitals 150 soldiers can be accommodated. The Red Cross has also arranged to take over the American Mission hospitals at Konia, Cesarea, Marsovan, Erzeroum, Sivas, Harpoot, Aintab, Latakia, Adana, Mersin, Mardin, Diarbekir and Van for similar purposes. These will provide accommodations for 1,000 sick and wounded soldiers in fifteen well-manned and equipped hospitals without cost to the government.

District Maternities.—The public hospitals in Berlin are making special provisions for the large number of obstetric cases expected shortly. Bumm suggests the establishing of small maternities, of ten to twenty beds, in the different districts of the city, so that they can be reached easily by the women. The public should be widely informed of the nearest maternities, and some beds should be kept free for each night. The authorities were spurred to action recently when a woman in labor was turned away by the leading public maternity. The socialist newspaper wrote up the case roundly denouncing the Universitäts-Frauenklinik, the institution in question.

Aid for Belgian Physicians.—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession, for the week ending May 29, 1915, lists the following contributions:

Dr. J. E. Talley, Philadelphia, Pa.		$ 10.00
Dr. Leonard W. Ely, Palo Alto, Calif.		5.00
Receipts for the week ending May 29		$ 15.00
Previously reported receipts		6,993.50
Total receipts		$7,008.50
Previously reported disbursements:		
1,625 standard boxes of food at $2.20	$3,575.00	
1,274 standard boxes of food at 2.30	2,930.00	
213 standard boxes of food at 2.28	485.64	
Total disbursements		6,990.84
Balance		$ 17.66

F. F. SIMPSON, M.D., Treasurer,
5 Jenkins Arcade Bldg., Pittsburgh, Pa.

Hygiene and Prophylaxis in the Field.—During the last few weeks, courses of lectures have been delivered at various points in Italy to instruct soldiers in prophylaxis of disease and hygiene at the front in general. For several months series of lectures to prepare medical men for work at the front have been held in some of the large cities. Conferences have also been held under the auspices of local medical societies, as at Ferrara, where special efforts were made to bring up to date the knowledge of the physicians in respect to typhus, epidemic meningitis, tetanus, bayonet wounds, traumatic neuroses, etc. Everywhere physicians have flocked to these conferences. The nonmedical ones were arranged by an organization formed for this purpose, the Associazione nazionale per l'istruzione del soldato e del popolo, and the Comitato nazionale feminile per l'intervento italiano. The date for the final examinations for the medical schools was advanced to bring them mostly into May.

Campaign in France Against Alcohol.—The prefects of police of five departments of Normandie, in northern France, recently summoned a conference to discuss ways and means to restrict the use of liquor, and voted a number of what they state are merely palliative measures until legislative restrictions can be imposed. For the latter they urge that the sale of spirits be suppressed entirely during the course of the war, and that the number of saloons should be restricted and no liquor be sold to soldiers, women or minors under 18, and that debts for purchasing liquor should rank with gambling debts. The prefect of the Eure department summarily prohibited the sale of alcohol throughout his department during the war, his decree being signed August 26. He specifies as "alcohol," rum, cognac, calvados, kirsch and brandy. The general in charge of the Rouen department issued a similar decree in May, only he specified that wine, cider and beer were not included in the prohibition, and that the sale of liquor was forbidden only to soldiers, French, British or Belgian, to women, to minors under 18, and to refugees and others receiving state aid. The decrees are given in full in the *Bulletin de l'Académie de Médecine,* May 4, and hailed as great progress as they emanate from laymen.

BERLIN LETTER

BERLIN, May 3, 1915.

Personal

The Cancer Research Institute connected with the Charité Hospital at Berlin has been in charge of Professor Klemperer until recently. His duties calling him elsewhere, Prof. F. Blumenthal, formerly Leyden's assistant, has been made director of the institute during Klemperer's absence at the front.

The chief of the military medical service in the eastern area of war, Obergeneralarzt von Kern, has been advanced to the rank of a general lieutenant, with the title of Excellency. Hitherto no military medical officer, with the exception of the chief of the entire service, von Schjerning, has ever had the title of Excellenz conferred on him. It is regarded as a further token of the appreciation by the kaiser of the achievements of the medical department, the Sanitätskorps, in the war.

The War

EXCHANGE OF PRISONERS

The exchange of severely wounded soldiers is being continued with France and has been begun with Russia. This is a humanitarian measure which meets the greatest approval of all involved. The hard fate of the permanently invalided can certainly be borne better in their home surroundings than in the enemy's country.

PARTIAL REMOVAL OF RESTRICTIONS TO BREAD

New decrees have been issued by the department of the interior, based on the advice of prominent experts summoned for the purpose from medical circles. Continued investigation as to the supply of wheat on hand led to the gratifying discovery that there is a larger supply available than had been supposed. Consequently larger proportions of wheat flour can now be used in making bread, so that conditions approximate normal once more. The supply of oatmeal is so extensive that it can be obtained without a "bread ticket."

FOUR HOSPITAL TRAINS

The number of hospital trains is constantly being added to, and has already reached almost 200.

HEADQUARTERS OF SUPPLIES FOR THE MILITARY MEDICAL DEPARTMENT

The central headquarters for the supplies for the entire sanitary service of the army and navy are installed in the Kaiser Wilhelm Military-Medical Academy at Berlin. The new goods as received are stored in the broad entrance hall. After they have been carefully inspected and approved, they are then arranged on rows of shelving which are installed through the rooms on the various stories. On these ranges of shelving are arranged all the apparatus, instruments, dressing materials and other things required for the medical and surgical work, everything stored in such a way that it is instantly available. During the winter the trucks were loaded with supplies in a heated shed to avoid injury of articles that might have been damaged by the cold. The shed was also lighted with electricity, as at times some of the work had to be done at night. The new methods of warfare have brought new requirements for the equipment of the medical service. For example, there are now special first-aid packages for aviators, and special litters for trench work. These litters are made so narrow that they can be easily carried through the narrow trenches. They have handles on all sides, and can be strapped on the back, so that a single person can thus carry a wounded soldier on his litter. Knapsacks fitted with surgical supplies are also provided. The drugs used are in tablet form or in sterilized solutions in small fused vials.

RAILROAD EQUIPMENT FOR PROPHYLAXIS OF CONTAGIOUS DISEASES

In Prussia, two hospital trains have been transformed into *Seuchenzüge* to aid in warding off epidemic diseases. Each train consists of a "clean" part, in which there is no fear of contagion, and a "contaminated" part. In one of the trains the first part has thirteen cars, the second, twenty-five. On one platform of twelve of the last cars stands an arrangement for sterilizing the clothing. These platforms are placarded on both sides to warn the brakemen to keep off. The brake handles further are painted red to warn against touching these brakes on the "contaminated" part of the train. None of the brakemen, conductors, engineers or others of the crew are allowed to pass through the "contaminated" part of the train. Any directions or orders they wish to give for the heating, lighting, etc., of the contaminated part of the train must be called from without to the persons in this part of the train. The latter are taught beforehand how to manage the heating and lighting apparatus in their part of the train. If it becomes necessary for others of the crew to enter the contaminated portion, they are required to wear an overgarment and to disinfect themselves under the medical officer's directions before they can pass to the "clean" part.

Car No. 14 is the intermediate link between the clean and the contaminated departments of the train. Here the baths and other special measures considered necessary are enforced before any one is allowed to pass from the rear to the front end of the train. In the "contaminated" part of the train, the platforms are kept wet with a solution of mercuric chlorid, and the brakemen have to scrape their shoes on a cloth wet with the solution and provided for the purpose as they leave the platform. They also have to wash their hands in a similar solution under the physician's orders. In the second train of the kind, the sterilizing boxes are inside the cars, so that the brakemen are free to attend to the brakes at either end of the car.

Women Students During the War

The conditions during the war have not greatly affected the number of women taking university courses. In the winter semester 3,914 women students were registered in German universities, which is an increase of 225 over the previous year. Of this increase, about 100 are in medical courses (944 as compared with 859) and 34 in dentistry (66 as compared with 32). About 25 per cent. of the women are in the Berlin University.

LONDON LETTER

London, May 18, 1915.

The Campaign Against Tuberculosis

A government report shows that up to the end of March, 1914, local authorities had submitted schemes for the treatment of tuberculosis relating to over 95 per cent. of the total population of England. Only five of the fifty county councils and six of the seventy-six county borough councils had not then prepared schemes. March 31 last, 7,898 insured and 14,201 uninsured persons were receiving dispensary treatment, and, in addition, 8,166 insured and 11,445 uninsured persons were under observation by the medical officers of approved dispensaries. On the same date, 4,555 insured and 1,231 uninsured patients (including dependents of the former), were receiving treatment provided in residential institutions by local authorities or at the cost of insurance committees. Up to June 20 last, 259 sanatoriums, hospitals and other residential institutions, containing at least 9,200 beds available for tuberculous cases, had been approved by the board. Approval was also granted to 255 dispensaries in England and seventy-three in Wales, while the appointment of 177 tuberculosis officers was sanctioned. In 1913 the number of cases of pulmonary tuberculosis notified in England and Wales was 96,553, representing 2.64 per thousand of the population, compared with 110,551, or 3.03 per thousand in 1912.

THE ALCOHOL PROBLEM

The drastic proposals of the chancellor of the exchequer for dealing with intemperance among a section of the men engaged in producing munitions of war (described in a previous letter), have been abandoned, as the opposition to them was too great. It was generally felt that to meet a local evil the chancellor was penalizing every one who consumed spirits or wine even in moderation. Moreover, our French allies, who are cut off from the rest of their European market, naturally objected to a measure which would restrict their trade with their one remaining important customer. A suggestion, made some weeks ago in the columns of the *Lancet* has been adopted in principle. This was that the sale of immature spirits, to the consumption of which by working men much of the evil was attributed, should be forbidden. It is now proposed that spirits under 2 years of age shall be compulsory bonded and a surtax levied on all spirits taken out of bond between 2 and 3 years of age. There is to be state control of all saloons in the munition area by a central board composed of representatives of the admiralty, war office and home office.

Libel Action Against the British Medical Association

I have reported in previous letters two actions against the British Medical Association by Stevens, the proprietor of a "cure for consumption," which was exposed in the defendant's publication, "Secret Remedies." In the first action the jury disagreed. In the second they gave a verdict for the association. Stevens has now appealed against this verdict on the ground that it was against the weight of evidence. The appeal has been dismissed.

The Shortage of Physicians

The shortage of physicians in civil practice is increasing in consequence of the demands of the army. The effects are shown in many ways. In the advertisements for resident physicians of hospitals and institutions, which used to be almost confined to males, the words "male or female" are now inserted. In some hospitals American physicians engaged in graduate study have been appointed to the resident posts—an entirely new departure. The remuneration of locum tenens some years ago was about $15 a week. After the passing of the insurance act it rose to from $25 to $35. Since the war it has further increased from $40 to $50, as the demand has far outrun the supply.

PARIS LETTER

Paris, May 13, 1915.

The War

THE WAR AND PUBLISHING

The breaking out of war last July caused great disturbance during the last five months of 1914 in the industries which have to do with the manufacture of books. The statistics published by the *Bibliographie de la France* furnish interesting indications as to the classes of books which have been most affected. As far as the medical sciences are concerned, there is a reduction during 1914 of about 176 publications. This difference between normal times and the present has been reduced to 133 by slight increases during the first seven months of the year in publications on clinical medicine, surgery, practical instruction in medicine, mineral waters and climatic stations. In the last subject the increase is due to more numerous editions of the *Gazette des Eaux*.

CARDIAC WOUND CAUSED BY A FRAGMENT OF A GRENADE WITH EXTRACTION OF THE PROJECTILE

During a recent session of the Académie de médecine, Dr. Beaussenat, surgeon of the national asylums, showed a patient, a young sergeant, who had been operated on for a cardiac wound and whose history seems unique. Oct. 1, 1914, the soldier was wounded by a fragment of a hand grenade which pierced the diaphragm, the pericardium and the entire thickness of the cardiac muscle, lodging in the right ventricle. The fragment was extracted February 17 last (that is to say, four months and a half after its introduction) and the heart was then sutured. Three days of intense dyspnea and imminent syncope were followed by a slight fever on the fourth, fifth and sixth day, and this was accompanied and followed by pulmonary complications which rapidly disappeared. A month after the operation, the wounded man could be regarded as completely recovered. At present, the heart functions normally.

The prolonged tolerance by the heart of a metallic foreign body had already been shown by two cases, reports of which have been published. In one case the wounded man lived for four months and a half; the second patient did not die until the end of the seventh month after the wound. In neither case, however, was an operation performed and the foreign bodies were not discovered until necropsy. The case reported by Beaussenat proves that exploratory cardiotomy is justified under such circumstances and that success may be hoped for.

PREVENTIVE TREATMENT OF PERITONITIS COMPLICATING TYPHOID FEVERS IN WAR

At one of the last sessions of the Société médicale des hôpitaux de Paris, Dr. V. Courtellemont called attention to the fact that in war time typhoid fever peritoneal complications are especially frequent because of the exceptional fatigue to which the patients are subjected and the unsatisfactory diet which they receive during their removal. The prevention of these cases of peritonitis is imperative because they are almost invariably fatal; appropriate preventive treatment, however, has very good chance of success. During this period the peritoneal reaction manifests itself by three signs: abdominal distention, vomiting and abdominal pains. The most frequent of these signs is the abdominal distention. As soon as the preperitonitic condition is recognized, the following treatment should be instituted: (1) immobilization on the back (no baths, lotions or wrappings; no lateral movements; no trunk movements); (2) the permanent application to the abdomen of an icebag wrapped in flannel; (3) complete withholding of liquids from the patient; (4) nourishment by means of subcutaneous injections of serum 1 liter per day (500 c.c. in the morning and the same amount in the evening). This treatment should be continued in most cases for three days.

MEASURES AGAINST CONTAGIOUS DISEASES

In response to a question of Dr. Vaillant, deputy from the department of the Seine, the minister of war has explained that orders have been issued to the armies that all prisoners shall undergo a summary medical examination as soon as possible after their capture. Before being removed to the interior of the country, the men and their clothes are to be cleaned and freed from lice and other parasites. Every prisoner whose condition of health is suspicious is to be isolated and kept under observation in a hospital for contagious diseases. All quarters which are occupied by our troops after abandonment by the enemy are to be cleaned and disinfected, if necessary.

A GIFT FROM HAVANA PHYSICIANS

The minister of war has just received a letter from a group of Havana physicians, former pupils of the Faculté de médecine de Paris, "desirous of showing in a practical manner the affection and gratitude felt for their teachers and numerous colleagues who are giving their services in the hospitals of the Red Cross and on the fields of battle." This letter, which bears the signatures of Drs. Francisco Dominguez, Agustin Varona y Gonzales del Valle, Jose A. Presno, J. B. Landeta, Gabriel Casuso, Diego Tamayo, F. Mendez Capote, Eusebio Hernandez, Pedro Lamotte, Julio Irtiz Cano, Octavio Ortiz Coffigny, M. Sanchez Toledo, Antonio Diaz Albertini and Louis Montane, accompanies a gift of 7,000 pounds of tobacco, 14,000 cigars, 25,000 packages of cigarettes, 7,000 liters of white rum, 50,000 pounds of sugar, 4 sacks of coffee, etc., to be distributed among the hospitals of the Red Cross. Dr. F. Dominguez wrote on behalf of the donors, expressing their good will toward their Paris teachers and comrades.

The Osiris Prize

The Osiris prize, which amounts to 100,000 francs ($20,000), is given every three years for "the most remarkable discovery in sciences, letters, arts, industry and in general any subject which concerns the public welfare." This year the committee of award has had to indicate the disposal not only of the prize for the current year, but also of the arrears of the prize of 1912, which was not given out at that time. After a very long deliberation (over two hours and a half), the committee decided to propose the following disposition of the prizes for the ratification of the general assembly of the five academies composing the Institut de France:

1. The Osiris prize for the year 1915 to be given as a reward for the discovery and application of the antityphoid vaccination, 50,000 francs being shared between Professors Chantemesse and Widal and 50,000 francs being given to Professor Vincent of the Ecole d'application de médecine et de pharmacie militaires du Val-de-Grâce.
2. Out of the unawarded prize of 1912, the sum of 60,000 francs ($12,000) to be devoted to the military works of the institute and the remainder to be held in reserve.

It is interesting to recall that the Osiris prize was awarded for the first time, in 1903, to Dr. Roux, director of the Pasteur Institute, for his work on diphtheria.

Marriages

Alfred Ervan Chesley, M.D., to Miss Geneva M. James, both of Lawrence, Mass., at Plaistow, N. H., May 20.

Lawrence Kirby Lunt, M.D., Boston, to Mrs. M. H. Donaldson of Scotland, at Brookline, Mass., May 17.

Charles Wilson Frey, M.D., Dallastown, Pa., to Miss Virginia D. Billet of North York, Pa., May 19.

John L. Foxton, M.D., to Miss Mabel Fuller, both of Huron, S. D., at Laurel, Neb., May 19.

Paul Henry Ringer, M.D., to Miss Eleanor Varick Morrison, both of Asheville, N. C., May 1.

R. M. Shaw, M.D., Alex, Okla., to Mrs. Myrtle Norman of Oklahoma City, recently.

William F. Sirak, M.D., Cleveland, to Miss Lottie Greenberg of Bay City, Mich., May 2.

Robert Hurka, M.D., to Miss Helen Conover, both of Verdon, Neb., May 15.

Deaths

George Wilkeston Guthrie, M.D., one of the best-known and most esteemed practitioners of Pennsylvania; died after a long illness, of bronchopneumonia followed by pleural effusion, at his home in Wilkes-Barre, May 31, aged 70. He was born in Guthrieville, Pa., and was graduated from the University of Pennsylvania, Philadelphia, in 1873. A year later he was elected secretary of the Luzerne County Medical Society and served the organization in this capacity for sixteen years when he was elected president. He was a member of the Medical Society of the State of Pennsylvania, and served as councilor and trustee for a long term, was president of this constituent association about 1900. He was a Fellow of the American Medical Association and from the time of the organization of the House of Delegates in 1902, until 1913, inclusive, he was continuously a member of that body; in 1912 he was made a member of the Judicial Council of the Association. He was also a Fellow of the American Surgical Association; and for many years surgeon to the Wilkes-Barre City Hospital and consulting surgeon to the Pittston Hospital. He was for a long time a member of the Wilkes-Barre Board of Education. Dr. Guthrie, both as a physician and a citizen, was one of the leading men in Pennsylvania. A man of integrity, a man of definite and strong opinion, but one who never lost sight of justice, Dr. Guthrie was a worthy and dependable councilor.

John Threadgill, M.D. University of Alabama, Mobile, 1874; a Confederate veteran; for several years proprietor of a sanatorium at Norman, Okla.; president of the Oklahoma Bank and Trust Company; organizer and president of the Oklahoma National Life Insurance Company; for two terms a member and for one term president of the State Board of Education; president of the Oklahoma City School Board in 1903; for two terms a member of the Oklahoma legislature and a member of the State Pension Board; died at his home in Oklahoma City, May 15, from heart disease, aged 67.

George Gustave Lempe, M.D. Albany (N. Y.) Medical College, 1888; a Fellow of the American Medical Association, and a member of the American Association of Anatomists; president of the Albany County Medical Society in 1910; lecturer on surgery and anatomy in his alma mater; assistant attending surgeon to Albany Hospital and consulting surgeon to the Benedictine Hospital, Kingston, N. Y.; surgeon of the Third Cavalry Squadron, N. G., N. Y., and detailed to duty with B Troop; died at his home in Albany, May 17, from myocarditis, aged 49.

Amos Walker Barber, M.D. University of Pennsylvania, Philadelphia, 1883; of Cheyenne, Wyo.; president of the Wyoming State Medical Society; governor of Wyoming in 1892, during the famous range war which was known as "The Cowmen's Invasion" when his wise counsel is said to have prevented interstate strife; in 1885, on duty at the Military Hospital at Fort Fetterman; said to have been the originator of the treatment of snake-bite by permanganate of potassium; died in Rochester, Minn., May 18, aged 54.

John Steele Mabon, M.D. University of Pennsylvania, Philadelphia, 1880; a Fellow of the American Medical Association and American Laryngological, Rhinological and Otological Society; for a time a member of the faculty of the

Western Pennsylvania Medical College; a specialist on diseases of the nose, throat and ear, of Pittsburgh, and formerly president of the Allegheny County Medical Society; one of the most prominent specialists of Pennsylvania; died at his home in West View, Pittsburgh, May 20, aged 58.

J. Guy McCandless, M.D. Jefferson Medical College, 1863; a Fellow of the American Medical Association and a widely known physician of Pittsburgh; for many years a member and president of the common and select councils and for one term director of public works of Pittsburgh, and for three terms a member of the State Board of Medical Examiners; surgeon of the One Hundred and Fifty-Second Pennsylvania Volunteer Infantry throughout the Civil War; died at his home in Pittsburgh, May 23, aged 75.

William Dougall, M.D. Northwestern University Medical School, Chicago, 1868; a Fellow of the American Medical Association; once president and later secretary of the Will County (Ill.) Medical Society; president of the Illinois Pure Aluminum Company, Lemont, and for a time chief surgeon of the Illinois and Michigan Canal; from 1879 to 1883, postmaster of Joliet; a veteran of the Civil War; died at his home in Joliet, May 18, from heart disease, aged 73.

George A. Stark, M.D. McGill University, Montreal, 1872; assistant surgeon of the Northern Pacific Railway at Mandan, N. D., and assistant physician at the North Dakota State Reform School; from 1883 to 1889, justice of the peace of Glen Ullin; for twenty-five years health officer of Morton County and for two terms county physician; died at his home in Mandan, N. D., May 6, from cerebral hemorrhage, aged 71.

Mark Delimon Stevenson, M.D. Rush Medical College, 1897; a Fellow of the American Medical Association and a member of the American Academy of Ophthalmology and Oto-Laryngology; vice president of the Summit County (Ohio) Medical Society in 1907, and president in 1908; co-editor of *Ophthalmology;* died at his home in Akron, Ohio, May 21, from septicemia, aged 39.

Hewlitt Whitty Oakley, M.D. University and Bellevue Hospital Medical College, 1904; a Fellow of the American Medical Association and one of the organizers of the Tulare County Medical Association; at one time connected with the medical staff of the S. R. Smith Infirmary, Staten Island, New York; died at his home in Portersville, Calif., May 21, from dysentery, aged 35.

R. Dorsey Coale, M.D. University of Maryland, 1912; Ph.D. Johns Hopkins University; for many years dean of the medical school of the University of Maryland; colonel of the Fifth Infantry, Md. N. G., during the Spanish-American War, and from 1886 to 1909, an officer of that regiment; died in University Hospital, Baltimore, May 17, from cerebral hemorrhage, aged 58.

Thomas H. Maxedon, M.D. Hospital College of Medicine, Louisville, 1887; a member of the Indiana State Medical Association and one of the best-known surgeons of Indiana; local surgeon to the Baltimore and Ohio Southwestern Railway; president of the Metropolitan Police Board of Vincennes; died at his home in that city, May 19, from cerebral hemorrhage, aged 53.

James S. McDonough, M.D. Atlanta (Ga.) Medical College, 1860; one of the oldest citizens of Knoxville, Tenn.; a member of the State Board of Medical Examiners of Tennessee since 1893; surgeon of the Sixty-Third Tennessee Infantry, C. S. A., throughout the Civil War; died at his home in Knoxville, May 16, aged 84.

Alfred C. Clark, M.D. Jefferson Medical College, 1869; a member of the Medical Society of the State of Pennsylvania; for eighteen years medical inspector of Northumberland County, Pa., for the State Board of Health and local surgeon for the Pennsylvania system at Sunbury; died at his home in Sunbury, May 16, aged 70.

William Richard Bevan, M.D. Marion-Sims-Beaumont College of Medicine, St. Louis, 1906; professor of pathology, histology and bacteriology in Epworth University, Oklahoma City; instructor and assistant professor of obstetrics in the University of Oklahoma, Oklahoma City; died recently from tuberculosis, aged 34.

George Clarence Gliddon, M.D. University of Toronto, 1914; of Union, Ont.; captain, Canadian army medical corps and R. M. O. tenth battalion, second brigade, first Canadian expeditionary force; who was seriously wounded at the battle of Langemarck in Flanders; died from his wounds, May 14, aged 26.

James M. McMasters, M.D. Rush Medical College, 1866; of Sauk Center, Minn.; assistant surgeon of Minnesota Volunteers during the Civil War, and acting assistant surgeon, U. S. Army, in 1867 to 1868, with duty at Fort Ridgley; died at the home of his daughter in Valparaiso, Ind., May 8, aged 73.

Edward McVicker Hamaker, M.D. Medico-Chirurgical College of Philadelphia, 1913; who after completion of his internship in the Philadelphia General Hospital, located in Muskegon, Mich., May 20, was found dead in his room in a hotel in that city, May 21, from heart disease, aged 24.

Charles Jewett Lincoln, M.D. Dartmouth Medical School, Hanover, N. H., 1895; a Fellow of the American Medical Association; physician to the Augusta (Me.) City Hospital, and supreme physician to the American Royal Circle; died at his home in Augusta, Me., March 14, aged 45.

Sigismund Cohn, M.D. University of Berlin, Germany, 1888; a Fellow of the American Medical Association and a member of the American Electrotherapeutic Association, and the German Medical Society; died at his home in New York City, May 18, from heart disease, aged 53.

William Jeff. Armstrong, M.D. Bellevue Hospital Medical College, 1883; a member of the Medical Society of the State of Pennsylvania; at one time a member of the Board of Education of Kane, Pa.; died at his home in that place, May 13, from heart disease, aged 61.

James Perry Walters, M.D. Miami Medical College, Cincinnati, 1876; formerly a member of the Illinois State Medical Society and secretary of the Wayne County Medical Society; a veteran of the Civil War; died at his home in Fairfield, Ill., May 9, aged 66.

Michael Freebern Gavin, M.D. Harvard Medical School, 1864; a Fellow of the American Medical Association; surgeon of the Fifty-Seventh Infantry, Mass. V. M., during the Civil War; died at his home in South Boston, May 20, from cerebral hemorrhage, aged 71.

William P. Dillon, M.D. McGill University, Montreal, 1904; of Ottawa, Ont.; major in the Canadian army medical corps and on duty with the Canadian contingent in France; died in General Hospital No. 2, in rear of the British lines near Ypres, France, May 13.

Frank Mills Douglass, M.D. Tulane University, New Orleans, 1905; a member of the State Medical Association of Texas, and formerly president of the Hill County (Tex.) Medical Society; died at his home in Itasca, Tex., May 17, from nephritis, aged 37.

Henry William Muller, M.D. New York University, New York City, 1898; formerly a member of the Medical Society of the State of New York and physical director of the Y. M. C. A.; died at his home in New York City, May 21, from nephritis, aged 44.

James Arthur Robinson, M.D. University of Pennsylvania, Philadelphia, 1882; a practitioner of Taunton, Mass.; who left on a trip to the Pacific coast on May 11; was found dead from heart disease in his room in the Rosslyn Hotel, San Francisco, May 22.

James M. Stevens, M.D. Medical College of the State of South Carolina, Charleston, 1852; surgeon of the Forty-Seventh N. C. Infantry, C. S. A., throughout the Civil War; died at his home near Leicester, N. C., May 17, from heart disease, aged 87.

John George Layton, M.D. Cleveland Homeopathic Medical College, 1895; of Independence, Ohio; died in the Cleveland State Hospital, April 15, from general paresis, aged 50.

Charles H. Jones, M.D. Tulane University, New Orleans, 1876; formerly of Greenville, Miss.; died at his home in Memphis, Tenn., May 6, aged 70.

Patrick H. Thompson, M.D. Tulane University, New Orleans, 1878; of Bluffton, Ga.; died in a sanatorium in Atlanta, Ga., May 10, aged 63.

John W. McMurray, M.D. Homeopathic Medical College, Cleveland, 1890; died at his home in Marion, Ohio, May 11, from arteriosclerosis, aged 75.

George A. Hibbert, M.D. College of Physicians and Surgeons, Chicago, 1893; died at his home in Chicago, May 15, from angina pectoris, aged 48.

Edna Thompson Mathews, M.D. Eclectic Medical Institute, Cincinnati, 1892; died at her home in Dayton, Ohio, May 5, aged 57.

Otto Henry Hund, M.D. New York University, New York City, 1880; died at his home in San Francisco, May 4.

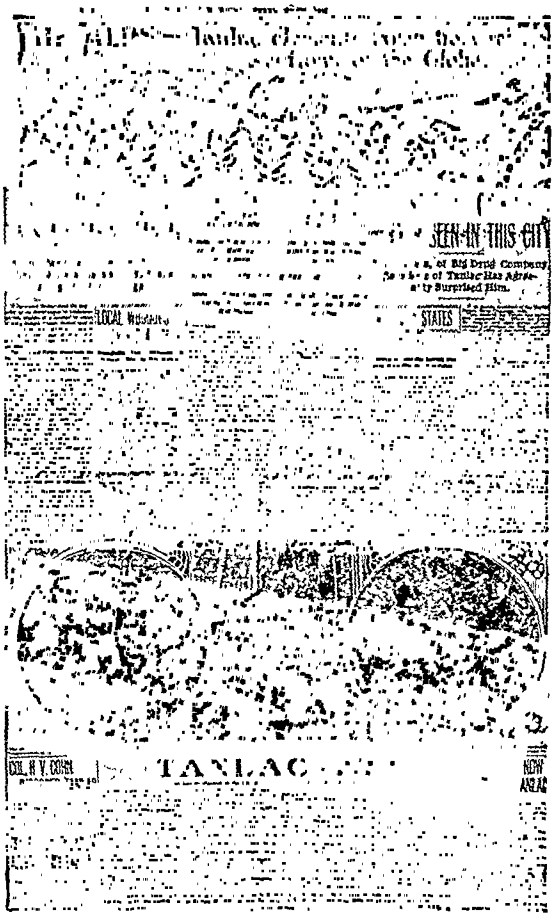
George Nixon Fish, M.D. Trinity Medical College, Toronto, 1898; died at his home in Toronto, May 1.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

TANLAC

Tanlac is a product of the Cooper Medicine Company, Dayton, Ohio. The controlling spirit of the Cooper concern seems to be one L. T. Cooper, who has been quacking it for many years. A few years ago it was "Cooper's New Discovery" that was being exploited by L. T. Cooper by the free vaudeville-medicine-show route. In 1907 Cooper was operating the "tapeworm trick" as one of his means of relieving the gullible of their money.



SEEN IN THIS CITY
STATES
TANLAC

Greatly reduced reproduction of an advertisement of Tanlac that appeared in a Louisville (Ky.) paper.

"Cooper's New Discovery" contained 17 per cent. alcohol and was sold as a "tonic and system purifier." Tanlac contains 17 per cent. alcohol and is a "tonic and system purifier."

During the last few months the Cooper concern has been advertising heavily and doing a big business in the southern states and—with the help of the newspapers—has doubtless relieved the people of the South of many thousands of dollars. The claims made for Tanlac are of the usual fraudulent type:

> "Tanlac . . . is not what is commonly called a medicine; it is more than a medicine, being the liquid maximum strength of medicinal properties of a plant discovered by Cooper's uncle, a celebrated scientist, which plant properties, together with other ingredients, obtained their high efficiency under the personal direction of Herr Jos. Von Trimbach, a native German chemist of note in charge of the Cooper laboratory."
>
> "Tanlac is called the magic medicine . . ."
>
> "Tanlac . . . preserves your health, gives you renewed energy, brightens your spirits, lengthens your life . . ."

"Catarrh" is Cooper's catchword. As with the old Peruna fraud every ailment is "catarrh" and the one infallible cure for "catarrh" is—according to Cooper—Tanlac! A number of inquiries having been received regarding this nostrum a bottle of Tanlac was secured and subjected to analytical tests. The report of the chemists of the Association's laboratory follows:

CHEMISTS' REPORT[1]

One original bottle of Tanlac, manufactured by the Cooper Medicine Company, Dayton, Ohio, was submitted to the Chemical Laboratory for examination. The bottle contained 8 ounces of a brown liquid having a wine-like odor, and also an odor somewhat resembling wild cherry. The taste was bitter, resembling gentian. The specific gravity of the liquid at 15.6 C. was 1.0205. Qualitatively, tests disclosed the presence of alkaloids, berberine being isolated and identified. Other alkaloids beside berberine were present, but not identified. Hydrastine and the commoner alkaloids were not found. Tests for emodin were positive. Acid caused precipitation, the precipitate having an odor of licorice. After purification, and treatment with ammonia, the ammonium salt of glycyrrhizic acid was detected. A relatively large proportion of glycerin was present. A small amount of tartaric acid was detected, which would indicate a wine. The residue, which weighed 11.1 per cent., was largely glycerine. The ash was 0.25 per cent. The amount of alcohol was found to be 15.70 per cent. of absolute alcohol by volume. The weight of the alkaloids was 0.017 per cent.

From the examination, it is concluded that Tanlac is probably a vinous extract containing essentially a bitter drug (such as gentian), an emodin-bearing drug (such as buckthorn, rhubarb or cascara), a berberine-bearing drug (in which hydrastine is not present, such as berberis aquifolium), glycyrrhizic acid (from licorice), flavored with wild cherry, and to which has been added a relatively large proportion of glycerine.

TANLAC SHIPPED TO MANY STATES

A Nashville (Tenn.) paper recently published this three-column advertisement of Tanlac.

Accompanying the bottle of Tanlac, were some "Tanlac Laxative Tablets." These contained phenolphthalein.

The findings of the chemists indicate that Tanlac is essentially a wine to which have been added some bitter herbs, a small amount of laxative and some glycerine. In October,

---

[1] This is a condensed report of the chemists' findings. The details of analysis will appear in the Reports of the Chemical Laboratory of the American Medical Association for 1915.

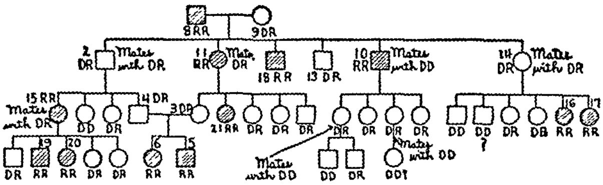
1914, the newspapers of Lexington, Ky., recorded the arrest of L. T. Cooper in connection with his method of exploiting his nostrum. There were several indictments against him to one of which he pleaded guilty, the others being filed. It now seems that Dr. A. T. McCormack, Secretary of the State Board of Health of Kentucky, is asking that these other indictments be revived and the case against this quack be reopened. It is possible that this may result in some restriction of the sale of this alcoholic tonic in the state of Kentucky. There is no doubt that other southern states whose sick are being mulcted by this concern could give equal protection to the public.

Correspondence

Polydactylism as a Hereditary Character

To the Editor:—In his paper on this subject (THE JOURNAL, May 15, 1915, p. 1640), Dr. Brandeis, while by no means deciding the question whether polydactylism is a dominant or a recessive characteristic, seems to assume that the mendelian dominance of either polydactylism or five-fingeredness is an irregular or an imperfect dominance. It does not appear—on carefully considering the family history with which he deals or the other family trees quoted—that such an assumption is really necessary.

Prima facie, I should be more apt to assume from these tables that polydactylism is a *truly recessive trait;* perhaps also venturing the suggestion that a proportion of the human race, larger than one would at first suppose, may have received from their parents factors that, under proper mating conditions, might bring this recessive trait to light.



Squares indicate males, circles, females. Shaded areas indicate affected persons (polydactyls).

Assuming these things, let us suppose that Individual 8 in Dr. Brandeis' tree is really RR in composition, and mates with 9, an apparently normal woman, but really DR in make-up. Obviously their offspring must be either DR or RR in kind: 10, 11 and 18, being polydactyl, are evidently RR; 2, 13 and 14 we must assume to be DR. Since one of Q's children is evidently RR, we must assume that Q's wife is also DR in make-up; of their three other children, one is likely to be DD, the others, including Individual 4, may reasonably be assumed to be DR. Individual 11, by our original assumption, is RR, and the polydactylism of her daughter, 21, proves that her husband is not DD, but presumably DR. (Digressing for a moment, it appears probable that 10, also RR, has mated with a DD, since his offspring are free from the recessive trait.) Returning to Individual 11 (RR as stated, and mated with DR), her daughter, 3, can only be DR: this daughter, 3, weds 4, her cousin, also probably DR, and their two children unite the R germ cells of each parent. If a larger family had sprung from the union of 3 and 4, it might have been anticipated that only one child out of four could have been a polydactyl: the fact that both their children are recessives is paralleled in an opposite way by the progeny of 11: here, instead of the mating of RR with DR giving equal numbers of RR and DR, we find in fact out of five children only one recessive, and that slightly. ("Six fingers left hand [the sixth] very rudimentary.") Dr. Brandeis' tree may then perhaps be amplified as above, symbols DR, RR, etc., being attached, and suggestions interpolated as to probable matings of individuals: the same explanations apply as in the original figure.

W. R. TYMMS, M.D., Gig Harbor, Wash.

Factors in Appendicitis

To the Editor:—In THE JOURNAL, May 8, 1915, p. 1584, a quotation is made from Rosenow to the effect that Heyde, Aschoff and others have called attention to the fact that the anatomy of the appendix favors strangulation of its circulation. These two authors are probably chosen for quotation because they are "made in Germany." One of them published his theory in 1911 and the other published his theory in 1912. *Among "the others" one will find a complete description of* this mechanical theory in a book entitled "Lectures on Appendicitis" by an American author, published in 1896. This book is to be found in medical libraries. It contains the statement that the serious complications of acute infective appendicitis are dependent on swelling of the internal coats of the appendix within the outer constricting sheath of peritoneum. When, for any reason, the inner coats of the appendix become compressed within the less resilient outer sheath of peritoneum, compression anemia follows. Tissues subjected to compression lose their natural degree of resistance to enteric bacteria, which promptly attack any such anemic tissues. Furthermore, proliferating endarteritis of the vessels of the appendix occurs as a result of toxic influence, and still further disables that organ. This American opinion was published fifteen years in advance of that of German authors who are chosen for quotation.

ROBERT T. MORRIS, M.D., New York.

Rigidity of the Right External Oblique in Appendicitis

To the Editor:—Textbooks and literature on appendicitis have laid so much emphasis on rigidity of the right rectus muscle as a symptom, that many cases of appendicitis have been neglected, because of lack of rigidity of the right rectus muscle. Rigidity of the right rectus, we all agree, is the most reliable of the symptoms which we have in appendicitis. There are a few cases, however, in which rigidity of the right rectus is lacking, but if looked for, there will be found rigidity of the right external oblique muscle. The cases of rigidity of the right external oblique muscle, and absence of rigidity of the right rectus, pursue a peculiar course. All cases are considered mild, many patients are up and around, some attending to business, and only a high polynuclear count shows the seriousness of the disease. In over twenty cases seen the past year, in which there was rigidity of the right external oblique, and not of the right rectus, the appendix has been retrocolic or retrocecal in every case. This is a point to which the attention of the medical profession should be drawn, to avoid serious neglect and carelessness.

H. E. RANDALL, M.D., Flint, Mich.

The Country Doctor

To the Editor:—May I carry a little further the comparison made by Dr. Flancher (THE JOURNAL, March 27, 1915, p. 1095), between city physicians and country physicians?

I practice in the country and go 20 miles to set a broken leg, attend a confinement, or treat a child for some common ailment. Like others in my situation, I often have to do without needed help, which a city man could procure. I have to be a "specialist" in everything. How many city doctors would manage all kinds of cases more successfully than we country "hayseeds" do? This is something they seldom think of. The city man writes the books but the country man has so much to study he seldom has time to write. Doctors are like trees. In the city they grow tall and straight, like trees in a thick forest, and reach a height we country doctors cannot attain to. The country doctors are like trees growing alone, where there is plenty of light and air, and where the winds have a full sweep. They grow thick and rugged. Not so much lumber can be cut from their bodies as from the tall, straight ones in the forest, but they have the strength to resist the fiercest storms.

A. C. AMES, M.D., Mountain Grove, Mo.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

POISONING FROM SODIUM CHLORID

To the Editor:—I have just heard of a case of sodium chlorid poisoning caused by the ordinary amount of sodium chlorid which is taken with food. Have you records of any cases of sodium chlorid *poisoning?* Are you able to cite literature on such cases.

Edward B. Markey, M.D., Hamilton, Ohio.

Answer.—Excessive doses of common salt may produce death, and, ordinarily speaking, this may be said to be the result of poisoning. It is, of course, possible that a patient may be hypersusceptible to sodium chlorid. In The Journal, Oct. 5, 1912, p. 1290, a case of poisoning with common salt is reported by O. H. Campbell, and an editorial in the same issue, p. 1297, refers to five other cases. In Queries and Minor Notes, Oct. 26, 1912, p. 1560, there is a consideration of poisoning from sodium chlorid when used in large doses as a drug.

LITERATURE ON PELLAGRA

To the Editor:—Please cite recent literature on pellagra to be used in the preparation of a paper on that subject.

O. M. Bourland, M.D., Van Buren, Ark.

Answer.—The following refer to articles which have appeared within the last year:

Child Federation Bulletin Service.—The Child Federation of Philadelphia, May 1, began the demonstration of a new idea in publicity work when it placed in 300 locations in the congested districts of the city, bulletins, 17 by 22 inches, on the "Prevention of the Fly." The bulletin boards are made of sheet iron and are so constructed that the bulletins printed on cardboard, may be placed in them without the use of paste, tacks or other holding means. Twenty social agencies were approached and each was asked to install a certain number of bulletin boards. The location of the boards was selected after a thorough survey of the city. The bulletins to be placed during the coming year number seventeen, and will treat of the general sanitary measures regarding the home, the hygiene of the family, care of the baby, etc.

Florida Homeopathic March Report

Dr. J. Burnie Griffin, secretary of the Florida Homeopathic Board of Medical Examiners, reports the written examination held at Jacksonville, March 5-6, 1915. The total number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 14, all of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago Homeopathic Medical College (1886) 80; (1887) 88; (1896) 90, 90; (1900) 86.		
Hahnemann Medical College and Hospital, Chicago (1894) 91; (1896) 90; (1906) 89; (1913) 85; (1914) 89.		
University of Michigan, Homeopathic Medical College	(1899)	92
Pulte Medical College	(1900)	82
Hahnemann Medical College and Hospital, Philadelphia	(1893)	85
Woman's Medical College of Pennsylvania	(1892)	81

Book Notices

The Modern Factory. Safety, Sanitation and Welfare. By George M. Price, M.D., Director, Joint Board of Sanitary Control in Cloak, Suit and Skirt and Dress and Waist Industries, New York City. Cloth. Price, $4 net. Pp. 574, with 257 illustrations. New York: John Wiley & Sons, 1914.

This volume shows evidence of careful, systematic preparation. It considers first the history of the factory and the legal definitions of the term "factory." The growth of the factory system is shown as it has occurred in various nations. The types of modern factories are illustrated, the poor contrasted with the good, and numerous suggestions given as to methods of construction. In a section on factory fires and their prevention, a history of important fires is given and the conditions are analyzed to show the possibility of prevention. An important chapter is that concerned with factory accidents and safety. Of recent years great attention has been given to these points. The author gives many illustrations showing methods of preventing contact with belts, cog-wheels, vats, moving saws and punches. Chapter V considers light and illumination, the prevention of glare, the regulation of light, and closes with a discussion of the standards of the Wisconsin Industrial Commission.

Under Factory Sanitation the chief points concerned are washing and toilet facilities, and the provision of a safe drinking supply. A chapter on welfare work discusses the various means of establishing accident and sickness insurance, profit sharing, old age pensions, food inspection, educational work, etc. Other chapters concern air and ventilation in factories, industrial poisons, gases and fumes, and a summary of factory legislation and factory inspection.

The list of appendixes includes a selected bibliography for further study, a partial list of the more important investigations authorized by federal and state legislatures, and suggestions for the organization and execution of exit drills. There is an adequate index, the book is beautifully illustrated, is printed on good paper and seems to be wholly complete and authoritative.

Bodily Changes in Pain, Hunger, Fear and Rage. An Account of Recent Researches into the Function of Emotional Excitement. By Walter B. Cannon, George Higginson Professor of Physiology in Harvard University. Cloth. Price, $2 net. Pp. 311, with 39 illustrations. New York: D. Appleton & Co., 1915.

"Fear, rage, pain and the pangs of hunger," says Dr. Cannon, "are all primitive experiences which human beings share with the lower animals. These experiences are properly classed as among the most powerful that determine the action of man and beasts. A knowledge of the conditions which attend these experiences, therefore, is of general and fundamental importance in the interpretation of behavior."

In this book Dr. Cannon has compiled a number of original articles which have appeared in current medical literature during the past year, and which represent work by himself and his associates in the Harvard Physiological Laboratory. An attempt has been made to arrange the discussions in a consecutive manner, and to explain technical terms so that the book may be understood by any intelligent reader.

Pathological Technique. A Practical Manual for Workers in Pathological Histology and Bacteriology, Including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By Frank Burr Mallory, A.M., M.D., Associate Professor of Pathology, Harvard University Medical School, and James Homer Wright, A.M., M.D., S.D., Pathologist to the Massachusetts General Hospital. Sixth Edition. Cloth. Price, $3. Pp. 536, with 174 illustrations. Philadelphia: W. B. Saunders Company, 1915.

Rapidly appearing modern advances in pathologic methods require the issuing of new editions of standard texts at frequent intervals. The sixth edition of Mallory and Wright is extended by the inclusion of many such methods; for example, Lange's colloidal gold test, the complement fixation test for gonorrhea, and Bielschowsky's silver impregnation stain for nerve fibers. The authors do not attempt to give all the available methods, but merely such as have proved practical and efficient in their experience.

The Chemistry of Colloids and Some Technical Applications. By W. W. Taylor, M.A., B.Sc., Lecturer in Chemistry at the University of Edinburgh. Cloth. Price, $2 net. Pp. 328. New York: Longmans, Green & Co., 1915.

This book is based on a series of lectures to advanced students in chemistry, and therefore discusses the subject from the standpoint of the chemist. There is, to be sure, a brief final chapter on the applications of colloid chemistry to biology, but it covers little of the great amount of work that has been accomplished in this field. Physicians who read German will be able to learn more from the books of Ostwald and Bechhold that will interest them, but, lacking facility in reading scientific German literature, they can at least secure the fundamental principles from this work. It is brief and clear.

Miscellany

Ben Franklin's Views

At my first admission into this printing-house I took to working at press, imagining I felt a want of the bodily exercise I had been us'd to in America, where press work is mix'd with composing. I drank only water; the other workmen, near fifty in number, were great guzzlers of beer. On occasion, I carried up and down stairs a large form of types in each hand, when others carried but one in both hands. They wondered to see, from this and several instances, that the Water-American, as they called me, was stronger than themselves, who drank strong beer! We had an alehouse boy who attended always in the house to supply the workmen. My companion at the press drank every day a pint before breakfast, a pint at breakfast with his bread and cheese, a pint between breakfast and dinner, a pint at dinner, a pint in the afternoon about six o'clock, and another when he had done his day's work. I thought it a detestable custom; but it was necessary, he suppos'd, to drink strong beer, that he might be strong to labor. I endeavored to convince him that the bodily strength afforded by beer could only be in proportion to the grain or flour of the barley dissolved in the water of which it was made; and there was more flour in a pennyworth of bread; and therefore, if he would eat that with a pint of water, it would give him more strength than a quart of beer. He drank on, however, and had four or five shillings to pay out of his wages every Saturday night for that muddling liquor; an expense I was free from. And thus these poor devils keep themselves always under.—*Autobiography of Benjamin Franklin.*

Neither Are We

It is with some interest we learn that there has been formed in some American cities a league of women for the purpose of compelling medical men to adopt a certain method of treatment. These good ladies have heard of the bliss of "twilight sleep" and of the ease of "painless labour," and while willing to produce children they are determined to do it with as little trouble to themselves as possible. This is so far a reasonable attitude, and one with which we do not quarrel. But the further step to the insistence on the rendering of labour painless by the use of scopolamin and morphin takes too many things for granted. It assumes, for instance, that scopolamin and morphin invariably produce the desired effect, and that they do so without appreciable danger. Unfortunately, neither of these propositions has yet been established. We are far from decrying the use of these drugs under suitable conditions and with the necessary care. But all our experience of them goes to show that their employment needs very careful attention — attention which it is not always possible to give in the conditions of ordinary obstetric practice. Whether these conditions will be modified in the future so as to permit of a wider use of these drugs remains to be decided, but their haphazard use at present is greatly to be deprecated. However, the ladies of the "Painless Labour League" have made up their minds. They are going to have their labours painless, and they are, as a first step, setting themselves to classify practitioners according to whether they use scopolamin or do not. The names of those who do not use the drug are to be put on the black list, and women are to be warned against employing them. We are glad to say that in these countries we are not yet used to having our therapeutic judgment compelled in this way.—*Medical Press and Circular*, May, 1915.

Statistics of Appendicitis in the Prussian Hospitals in 1912

Appendicitis seems to have greatly increased in recent years. Up to the year 1905 in the various hospitals of Prussia these cases were included in the group of peritonitis, of which the total number had increased from 896 (399 men, 497 women in 1877, to 15,918 (8,402 men, 7,516 women) in 1905. From 1906 on, the cases of appendicitis and peritonitis were tabulated separately, and it was found that while the former increased greatly, the latter did not increase in any noticeable quantity. The statistics from 1906 to 1912 showed that the cases of appendicitis in this period were 16,781, 19,285, 22,813, 25,689, 31,425, 38,555 and 41,503, whereas the statistics for peritonitis were 2,390, 2,498, 2,512, 3,710, 4,401, 3,459 and 3,628. In 1906 there were 9,184, or 54.73 per cent., men, and 7,597, or 45.27 per cent., women. In 1912 there were 21,225 men, or 51.14 per cent., and 20,278 women, or 48.86 per cent. The death rate in this disease was 7.7 per cent. in 1906 as compared with 5.45 per cent. in 1912 for men, and 5.45, as compared with 3.61, for women. The number of operations was much greater among the young than among the adult, and the mortality proportionately greater according to the youth of the patient. There seems to be no definite increase in mortality among the adults as related to increasing age.

Damages for Injuries Causing Epilepsy

(Louisville & N. R. Co. vs. Winkler (Ky.), 173 S. W. R. 151; Galveston, H. & S. A. Ry. Co. vs. Roemer (Tex.), 173 S. W. R. 229)

The Court of Appeals of Kentucky affirms, in the first case, a judgment for $2,500 damages in favor of the plaintiff, Winkler, for personal injuries he received in an accident on a freight train on which he was serving as a conductor. The court says that while Winkler was seated in the caboose he was pitched forward about 10 feet, and his head struck the water cooler in the front end of the car. A gash was cut to the bone on the right side of his head, and he suffered other injuries which at the time he thought were of a minor nature. It was contended that the damages were excessive because, before this injury, Winkler was suffering serious consequences from an accident which happened to him about five years before. The cause of that accident was not explained, but it appeared that he received a blow on the left side of his head, and he admitted that he had one spell of epilepsy apparently traceable to it. Other witnesses testified to having seen him have as many as a dozen epileptic fits during the five years preceding, but the evidence showed that they were not frequent, were of short duration, and, with perhaps one exception, there was no interference with the performance of his duties as conductor. In the injury here complained of he received a depressed fracture of the skull on the right side of his head. From January 3, the time of the accident, to January 26, when he returned to work, he was under the care of a physician most of the time, and from then until October he worked most of the time. He then had to give up his work entirely because of the increasing frequency and severity of the epilepsy. Medical testimony showed that after this last injury each spell would affect him for several days; that he became extremely nervous, and lost weight; that he had a twitching and jerking of the muscles in his face and jaws, and impediment in his speech, and the neck muscles had a certain amount of paralysis numbness; that his sight and hearing were impaired, and that his mentality had become very weak. A physician who examined him a few months before the accident, and again in December following, attributed the origin of the epilepsy to the old injury on the left side of the head, but said that the last injury on the right side had greatly accentuated the trouble. Under all the evidence, the court is unwilling to say that the verdict was excessive.

In the second case, wherein the plaintiff Roemer, in attempting to descend from the top of a freight car, was precipitated to the ground by a handhold giving way, the Court of Civil Appeals of Texas says that the case was peculiar, and there was presented to the jury a great mass of testimony pro and con on the question of whether plaintiff Roemer feigned the symptoms of epilepsy or whether he really suffered from terrible convulsions. This question was solved in his favor, and the court must take it for granted that he was afflicted as he claimed to be. If the testimony in his favor was true, at the age of 27 he received injuries which made him an invalid for life, and his affliction was such as to cause him constant dread, mental depression and much suffering. The court cannot say that a verdict of $20,000 in his favor was excessive, and a judgment for that amount is affirmed. The testimony of a physician was admissible, although he had great difficulty in determining whether he merely suspected that the plaintiff's fall and injury caused the condition in which he found him, or whether it was his opinion that such was the case, but finally stated that it was his opinion.

Hospital Not Liable for Death from Smallpox

(Jones vs. Sisters of Charity of the Incarnate Word (Tex.), 173 S. W. R. 639)

The Court of Civil Appeals of Texas affirms a judgment in favor of the defendants, whom the plaintiff had sued for damages for the death of his wife, who died from smallpox after she had been placed in the defendants' hospital to have an operation performed on her. The court says that, among the facts established by the undisputed evidence, it appeared that a physician had advised that it was necessary to have the operation, whereupon Mrs. Jones' son asked the physician to make arrangements to take his mother to the defendants' hospital. This the physician did, and notified the son, who then took his mother to the hospital, where they were met by one of the Sisters, and Mrs. Jones was given a room in a new building which had been recently added to the hospital, with which it was connected. At that time there was a smallpox patient on the opposite side of the hospital, and on a different floor from that on which Mrs. Jones was placed. The Sister who received Mrs. Jones did not inform her or her son that there was a case of smallpox in the hospital, and they were both ignorant of that fact; but the physician, who acted for Mrs. Jones and her son in making the arrangement with the hospital authorities, knew when he made the arrangements of the existence of the case of smallpox in the hospital. Other cases of smallpox thereafter developed, and, on the fourteenth day after Mrs. Jones was operated on, and when she was fully convalescent from the operation, she was stricken with smallpox, and died from that disease in a few days. However, there had never been a case of smallpox in the room, or in the portion of the hospital in which Mrs. Jones was placed, and no case except hers developed in that portion of the building. The court agrees with the trial judge that the facts were not sufficient to require the submission to the jury of the question of the defendants' liability for damages for the death of Mrs. Jones. There was no evidence of any intentional concealment on the part of the hospital authorities of the existence of the case of smallpox. Mrs. Jones' physician, who knew of the existence of the smallpox therein when he made the arrangements for her to enter the hospital, evidently thought it perfectly safe for her to go there, or he would have advised her to go elsewhere to be operated on. The health officer of the city, who gave directions as to the quarantine of the first patient, did not prohibit the reception of other patients in the hospital. The court cannot see how the Sisters could be held negligent for doing that which the most eminent medical authorities, with a full knowledge of the situation, regarded as safe. The plaintiff's wife in some unaccountable way may have contracted the disease from cases which occurred in the hospital, but the hospital authorities could not, in the circumstances, have reasonably anticipated that she would contract the disease, and could not therefore be held to have been guilty of negligence in failing to inform her when she applied for admission that there was a case of smallpox in the hospital. The trial court instructed the jury to find a verdict for the defendants, and rendered judgment in accordance therewith, which judgment should be affirmed.

A Rupture Caused by Strain is an Accident or Untoward Event

(Poccardi vs. Public Service Commission (W. Va.), 84 S. E. R. 242)

The Supreme Court of Appeals of West Virginia holds that a rupture caused by a strain while at work is an accident or untoward event, arising in the course of employment, and compensable under the workmen's compensation act. Proof of apparent previous good health, a heavy and unusual lift in the course of work, discovery of the rupture on the second day thereafter, death from surgical operation for relief thereof, and opinion of the operating surgeon that the rupture was caused by the lifting, is sufficient to establish accidental injury in the course of employment, within the meaning of said act. The court says that, responding to medical criticism of the theory of rupture by strain or exertion, the Washington Industrial Insurance Commission has adopted rules requiring proof, in cases of claims predicated on hernia: (1) That its origin was recent; (2) that it was accompanied by pain; (3) that it was immediately preceded by accidental strain in hazardous employment; and (4) that it did not previously exist. Similar rules have been adopted by the commission. Notwithstanding the criticism calling forth these rules, they impliedly admit possibility and probability of rupture from a strain, when the strain and rupture are in close relation. So does an article by the attorney for the Michigan compensation board, published in the National Compensation Journal, brought to the attention of the court by the brief for the commission. Both the rules and the thesis admit the English proposition that an internal injury, resulting from a strain while at work, is an accident, within the meaning of the act, and their limitations or restrictions on proof of the fact have not been judicially approved.

May Inquire About Angle at Which Roentgenograms Have Been Taken

(Baltimore & Ohio Railroad Co. vs. Whitacre (Md.), 92 Atl. R. 1060)

The Court of Appeals of Maryland, in affirming a judgment for damages for personal injuries in favor of plaintiff Whitacre, says that several exceptions were taken relating to the taking of a roentgenogram of the hip bone, which was claimed to have been fractured—whether the angle at which taken would or would not tend to disclose or conceal any such fracture. Evidence had been given by physicians of the fact of fracture, discovered by manipulation; but the use of photography in cases of this character is now so universally recognized that it is properly regarded as evidence of the strongest sort in any such case, and yet, as is well known, the lights or shadows produced by the angle of light may make a material difference in the appearance. It was therefore entirely proper that the witness should be fully examined on this point.

Mistakes.—The cynical philosopher laments the pity that in life we only get our lessons when they are of no use to us. It is worth while, nevertheless, to keep burning brightly that purifying fire, the fear of making a mistake, remembering in all humility that most mistakes are in reality avoidable, avoidable simply by method, the harness without which only the horses of genius can travel.—Adolphe Abrahams, *Practitioner*, London, March, 1915.

AMERICAN NEUROLOGICAL ASSOCIATION

Forty-First Annual Meeting held at New York, May 6-8, 1915

The President, Dr. George W. Jacoby, in the Chair

Postnatal Growth of the Brain Under Experimental Conditions

Drs. H. H. Donaldson, S. Hatai and King, Philadelphia: The general results of studies on the rat's brain are applicable to the human brain. Postnasal increase in the weight of the brain is due almost entirely to the enlargement of cell elements already present at birth. The increase in brain weight between birth and maturity is, in the rat, about ninefold. This corresponds to a doubling on the average of the initial diameters of the cells. Increase in size is most evident in the cell bodies of the neurons, but the formation of the myelin contributes more than any other single process to the increase in weight. Under all experimental conditions, the proportional weights of the divisions of the encephalon remain the same (except in the case of the bulbi olfactorii and flocculi). The conditions under which studies have been made are here grouped in accordance with their general effects on brain weight: 1. Unfavorable conditions. Domestication; some defective diets; disease (lung disease). 2. Indifferent conditions. Quantitative underfeeding with wholesome diets; some defective diets; inbreeding; gonadectomy. 3. Favorable conditions. Highly varied diets; exercise. Conclusions and applications.

Relation of Structure and Function in the Nervous System

Dr. Stewart Paton, Princeton, N. J.: The first period of life is that preceding the incidence of the nervous system as an active factor in the mechanism of adjustment. It is characterized by a few responses which are primitive in character. Only in the lower vertebrates do we find that any movements of the body take place during this primitive period of embryonic life. We have a very delicate and fairly defined proof that the nervous system is beginning to play its rôle. We have another important sign in the incidence of neurofibrillation. The appearance of the neurofibrils is probably one of the finest indications that we have of the incidence of function of the nervous system. The heart beats have begun and very probably are initiated without the interference of the nervous system. The heart may be looked on as an elaboration of a function which exists in chemical functions. As soon as the nervous system comes in, a great change takes place. What do we find in the nervous system at this time? We find something very striking indeed, and I believe something that throws great light on practical neurologic problems. In the first place, we find that an enormous preparation has gone on in the whole system preceding the incidence of function. It is really almost startling when one sees the great preparation in the spinal cord, the middle and the upper part of the medulla which has taken place in the differentiation of tissue. The most striking sections you will find in the region of the development and persistence of the ancestral type and enormous development of the cranial nerves. Undoubtedly these developments of the cranial nerves are transmitted to us from our ancestors lower down in the scale. Then if we go a little higher up in the medulla there is a very great development of the trigeminus, and in the embryo at this stage you can readily trace three branches coming off from the trigeminus. If we go one step higher in the medulla we come to the third nerve, which has no possible use at this stage of the life of the embryo, and yet is fully developed. What does this mean? The other point is that if we take this embryo just before the responses have begun, we find some very interesting conditions that I think will interest you practical neurologists. We find that such organs as the heart are definitely supplied with neurofibrils. You can trace out the whole cardiac mechanism. In addition to that you will find that an organ like the thymus has an enormous nerve supply. At an early stage, before the reactions of the body begin, the thymus has a definite and really an enormous nerve supply.

DISCUSSION

Dr. James J. Putnam, Boston: I would ask Dr. Paton whether he would be willing to accept all the conclusions to which the view that structure does really and truly precede function would logically lead. It is doubtful whether he would be willing to accept the conclusion that everything we know, learn and think as human beings, love of justice, honor and truth, are really nothing but the expression of structure, which itself is nothing but the expression of a rhythmic chemical process taken in the usual meaning of that term. It seems to me that is the conclusion to which we must come. Either structure precedes function or function precedes structure. From our own observation of ourselves, of thoughts and wills, we would think that function precedes structure. These researches of Dr. Paton's seem to indicate the reverse.

Dr. Philip Coombs Knapp, Boston: One simple illustration that structure must necessarily precede function can be brought out from this fact: We are conscious of our functions. We are by no means conscious of the structure. The absolute necessity of the structure preceding function is shown by the fact that unless we have a proper visual apparatus, the person remains blind and never can see. But any one who has experience in teaching ought fully to realize that it is not the vague transcendental desire to know which accomplishes the acquisition of knowledge, but rather the ability of the student to grasp the idea and to develop his knowledge. Experience in teaching shows that in spite of the best-developed schemes of instruction, in spite of every desire on the part of the pupil to learn and in spite of every effort of the teacher, a certain percentage of the pupils, by reason probably of a defect of structure, are going to remain hopelessly stupid, a condition against which one regards oneself as powerless.

Dr. Stewart Paton, Princeton, N. J.: So far as guinea-pigs are concerned, my statements are true. The criticism was very well taken about the possibility of function preexisting. Of course I had only a few simple reactions in mind. As to the other higher reactions, I think it will be a long time before we get to them. I hope my hearers will not take what I have said dogmatically as applied to the human being, and think of me only as an enthusiast in regard to the guinea-pig.

Ventricular Hemorrhage

Dr. Alfred Gordon, Philadelphia: I have seen seven cases of extraventricular hemorrhage and five cases of primary intraventricular hemorrhage. Erosions of the walls of the ventricles, rupture of the vessels of the choroid plexus and miliary aneurysms were found in the five cases. In all the cases, profound changes of all layers of the walls of the vessels and especially in the intima were present. I would call special attention to the following symptoms: sudden onset without premonitory symptoms, profound coma at the outset and continuing for several days without improvement, absence of genuine paralysis, absence of rigidity and contracture during the days following the seizure, and absence of the toe phenomenon. All these symptoms were so uniformly present in every one of the five cases of primary ventricular hemorrhage that pathognomonic inferences are permissible. In three cases there was a displacement of the brain tissue on the side opposite the hemorrhage. It is possible that the profound comatose state was due to this factor, and hence a decompression on the sound side may be of benefit. Accordingly, an operation was performed in one case, and considerable amelioration of the comatose state was obtained. Unfortunately, the other patients did not give their consent for surgical intervention.

DISCUSSION

Dr. Philip C. Knapp, Boston: I have seen a number of cases of intraventricular hemorrhage, most of them, however, of the secondary variety. I can hardly agree with the symptomatology which Dr. Gordon has given. In the ordinary symptomatology of the case, it has differed very little from that of an ordinary case of ventricular hemorrhage, excepting that the coma has been a little more sudden perhaps, and naturally distinctly more profound. In practically every case there have been distinct signs of hemiplegia as we ordinarily detect them in a person who is comatose. The one striking feature, however, in all the cases of ventricular hemorrhage has been that, although the duration of life is too short for contracture to develop, there has been a distinct rigidity of both sides. In no case have there been generalized convulsions. In a number of cases confirmed by necropsy I have felt that the rigidity and twitchings of the limbs are so characteristic as to warrant the diagnosis of intraventricular hemorrhage.

Dr. Alfred R. Allen, Philadelphia: At Dr. Spiller's instance a number of years ago, I studied in his laboratory the cases of ventricular hemorrhage with particular reference to the rigidity and twitchings. As I remember the specimens, in Dr. Spiller's cases they did not bear out the theory that of necessity there was any relation between rigidity and twitchings and ventricular hemorrhage.

Dr. Ernest Sachs, St. Louis: It is essential to recognize these cases, and if they are recognized, it seems that it is misdirected effort to do anything but try to approach the hemorrhage itself. To try merely to relieve pressure without trying to remove the extensive hemorrhage which is present seems unwise. I did not hear Dr. Gordon mention one symptom which has been described as rather characteristic of ventricular hemorrhage, and that is excessive temperature. I have been rather interested in this point from the physiologic point of view. It has been asserted by a number of experimental physiologists that this symptom is due to irritation of the fine fibers that lie along the floor of the ventricle. I have never been able to substantiate that, and am rather anxious to hear whether these cases, if they are pure ventricular hemorrhages, show that symptom.

Dr. E. E. Southard, Boston: Relative to the hyperpyrexia in ventricular hemorrhage, there are sequestered cases in which the rupture of the vessel is of infectious origin. About ten years ago I had occasion to report two cases of bacterial apoplexy in which the organism of the streptococcus was found; these hemorrhages were from erosions in the wall.

Dr. Alfred Gordon, Philadelphia: In reply to Dr. Knapp's remarks with reference to hemorrhage, I would state that, as Dr. Knapp saw only secondary hemorrhages, his remarks in reference to this have no bearing on the subject discussed by me because I spoke particularly of primary hemorrhage. The five cases of the lateral ventricles alone were all uniformly accompanied by paralysis, no toe phenomenon and marked patellar reflex on the paralyzed side. In reference to the question of temperature, the primary case has at first no rise of temperature.

Intracranial Telangiectasis

Dr. Ernest Sachs, St. Louis: I report two cases, both having jacksonian convulsions, but no other evidence of intracranial pressure. The eyegrounds were normal and the Wassermann reaction negative. In the one case, on the opening of the dura, a huge bluish mass of vessels protruded, which were so dense in places that the underlying cortex could not be seen. This mass lay over the motor area. There were no branches connecting with the dural vessels. In the second case the process was entirely confined to the dura, there being connections, however, between these vessels and the cortical vessels. Ligation of all these vessels relieved the symptoms and resulted in a cure. There are a number of cases in the literature which resemble one or the other of these cases, but they have usually been called angioma. A study of these cases, however, has led me to believe that these are not true angiomas but congenital tumors—telangiectasis. It seems essential to distinguish between true angioma, a neoplasm, and these congenital conditions. When reclassified they constitute a group which must be kept in mind in every case of jacksonian epilepsy. The clinical picture is quite a definite one: 1. Attacks of jacksonian epilepsy occurring at long intervals in nonsyphilitic young persons. 2. Unconsciousness of long duration. 3. No evidence of increased intracranial pressure. 4. A very slow progression of symptoms. 5. Telangiectases on the head or face. For this condition I suggest the name "intracranial telangiectasis."

DISCUSSION

Dr. M. Allan Starr, New York: The distinction Dr. Sachs has made is an exceedingly important one and should by all means be adopted. I erroneously, as I now see, reported some years ago as an angioma a case quite similar to the second case of Dr. Sachs. That was a wrong classification; it was a case of telangiectasis. The case was an interesting one clinically. It came to operation and Dr. McCosh tied off these vessels. The patient was a boy of 17 who was brought to me from Charleston, S. C., to the Presbyterian Hospital because he was suffering from very peculiar attacks. These attacks had occurred for a year. They had begun at the age of 15. They were characterized by a sudden severe, intense pain in the pyramidal region on the left side. The pain was located over an area the size of a half dollar. The attack would begin gradually, and for three days he was in the most intense agony, and the agony was so great that by the end of the second day he was in a state of acute mania. He was entirely uncontrollable, fighting every one who came near him, and these attacks of mania had been increasing up to the time he was brought to New York. He suffered from these attacks at two weeks' intervals. No diagnosis had been made; there were no localizing signs. Between the attacks he was entirely normal in every way. There was no choked disk, and the condition was quite a mysterious one. The attacks appeared to resemble in a way attacks of cortical epilepsy, although there was absolutely no spasm. There was an area of tenderness over the skull where he felt pain, which remained between the attacks. McCosh decided it was worth while to make an exploratory trephining operation. He was trephined over the area of tenderness, and the dura was apparently normal; but on cutting through the dura there was found one of these conditions of telangiectasis. There was a mass of veins on the surface, and they resembled more a mass of fishworms than anything I could think of. The mass was tied off. The boy made a prompt recovery. He had temporarily a condition of complete astereognosis with ataxia of the right hand which, after three days, passed away. I heard from him two and three years after the operation, and he had been perfectly well up to that time.

Dr. Alfred Gordon, Philadelphia: In the proceedings of the Neurological Society of Philadelphia, published in the *Journal of Nervous and Mental Diseases* several years ago, you will find a description of a case almost identical with that of Dr. Sachs. It was that of a young man of 30, who for fourteen years, if not more, had attacks of convulsions in the right leg alone; never in the arm. The attacks were accompanied by loss of consciousness. Dr. DaCosta opened his skull on the opposite side in the upper portion and in the area corresponding to the center, and he found a square shaped appearance of the vein, surrounded by four veins as large as a little finger. The veins were ligated, and the patient made a good surgical recovery. He developed a mild asterognosis in the right arm, and the convulsions ceased for a while. About six weeks later the convulsions returned. The patient later on came to see me again, and said that on exceedingly rare occasions he would have an attack.

Dr. E. B. Angell, Rochester, N. Y.: I had a case of jacksonian epilepsy develop in a youth of 16 or 17. The attacks were so characteristic that it was easy to locate the lesion. The boy was operated on by Dr. Zimmer of Rochester very successfully. In this case we found the same condition as that described by the speakers. This patient recovered and has stayed well for fifteen years.

Dr. J. Ramsay Hunt, New York: Since Cushing's paper of a few years ago, I have been on the lookout for such cases with intracranial complications. I recall three cases. One was an old infantile hemiplegia in which there was a contralateral hemiplegia with epilepsy. The other case was that of a man who had a trigeminal nevus and who in his fiftieth year developed epilepsy. The epilepsy, however, was not of the jacksonian type. It was interesting, however, that always before the attack of epilepsy he would have a period, sometimes several hours, of severe pain directly beneath the trigeminal nevus, so there may have been in such a case a connection between his epilepsy, which was generalized, and the vascular lesion of the dura. One man I saw had a congenital bunch of veins, and all through his life had been subject to periodical headaches somewhat suggesting migraine. He states that before these headaches these veins would always begin to swell. Of course the relationship between the veins and the headaches is obscure, but I thought it always well to bear in mind the possibility of intracranial complications in these cases of trigeminal nevi.

Mental Disturbances in the Feebleminded

Dr. William N. Bullard, Boston: The character of attacks of mental disturbance in the feebleminded is quite distinctive. In a person who shows only the ordinary conditions of feeblemindedness or idiocy, there occurs without any exciting cause sufficient under ordinary conditions to produce such an effect a sudden outburst of violence or temper. They scream, strike, kick, bite, destroy clothing and furniture and often require forcible restraint; they are obscene and profane. The attack lasts only one or a few days. There are usually prodromal symptoms such as listlessness, indifference and unusual actions.

Case of Wilson's Disease—Progressive Lenticular Degeneration

Dr. Frederick Tilney, Brooklyn: This case presented a typical syndrome of progressive lenticular degeneration, as described by Wilson. It ran a moderately acute course, terminating in death in fifteen months. The outstanding clinical features were the marked hypertonicity of the somatic musculature and the evidence of extreme toxicity. A preliminary report of the pathologic findings in the brain is given, and with this the histologic findings of the spinal cord, liver, spleen, kidney, thymic remains, thyroid, heart, lungs and suprarenal bodies.

DISCUSSION

Dr. H. H. Hoppe, Cincinnati: I had a case in a woman of 45 which presented quite a number of the features of Wilson's disease. There was hypertonicity associated with constant athetoid movements. The legs were constantly in a state of motion and the feet inverted. There are no pathologic changes in the reflexes, excepting that they are increased. The woman's mental state is practically normal, excepting that she is constantly in a state of rather pleasant frame of mind.

Dr. A. R. Allen, Philadelphia: Wilson has so limited his disease, so exactly described what it is pathologically as well as clinically, that it is very difficult to make a diagnosis of Wilson's disease pure and simple, outside of the necropsy room.

ASSOCIATION OF AMERICAN PHYSICIANS

Thirtieth Annual Meeting held at Washington, D. C., May 11-13, 1915

The President, Dr. S. J. Meltzer, presiding

SYMPOSIUM ON CIRCULATION

Important Contributions to Clinical Medicine During the Past Thirty Years from the Study of Human Blood Pressure

Dr. Theodore C. Janeway, Baltimore: In Flint's "Practice of Medicine," published in 1886, there is a passage referring to an increase of blood pressure in cases of small granular kidney and in cases of apoplexy. This showed an appreciation of the problem from facts learned by the unaided senses. A little later, Delafield, in this association, spoke of cases with arterial narrowing, with increased intravascular tension, but no measurements of pressure were referred to. In 1889, Stengel read a paper on athletics, but there was no mention made of blood pressure observations. In 1903, Cabot presented observations on blood pressure in man, and in 1904, there was a second paper by Cabot on observations of blood pressure by the sphygmomanometer. Since then the programs have always contained some titles bearing on this subject. What has been the real gain? There has been developed an easily available method by which any physician can gain by measurement essentially accurate information concerning both the systolic and diastolic pressures in the arteries. It has made a clinical entity of essential hypertension, of cardiovascular disease. It has disclosed the high pressure of the eclamptic state, and the low pressure of amyloid kidney. It has revealed the curious fact that in aortic regurgitation the pressure is higher in the leg than in the arm.

The study of average human blood pressure in connection with life insurance statistics has constituted an important and distinctively American line of research; Fisher's statistics are most important and indicate the normal increase of blood pressure with age. The tendency is to agree with Lauder Brunton and Cooke that 135 mm. to midlife and 145 mm. thereafter mark the limits of normal maximum variations in man. We have learned, in individual cases, however, not to view hypertension with so serious a prognostic eye. From the therapeutic standpoint, the recognition of the greater importance of cardiac conservation and adequate circulation than reduction of abnormally high pressure has been a very important contribution to our knowledge. The beneficial effect of digitalis in maintaining compensation in these states is also a valuable contribution. The study of the effects of caffein, strychnin and other allied heart stimulants in connection with observations of the blood pressure has resulted in disillusionment with respect to the value of these agents. Perhaps the most important of all the contributions to clinical medicine growing out of the study of human blood pressure have been the theoretical considerations having to do with the origin and explanation of the degenerative cardiovascular diseases, and these considerations must continue to be the basis of further study.

Dyspnea in Cardiac Diseases

Dr. Francis W. Peabody, Boston: *Acidosis plays an insignificant part in the dyspnea of simple cardiac diseases. Acidosis is a more important factor in the dyspnea of cardiorenal disease.* The second conclusion might be expected from the facts that acidosis is often present in cardiorenal disease and that dyspnea is often present in the absence of cyanosis. To these facts may be opposed the objections that the acidosis is usually slight and that the dyspnea is clinically different from the hypnea of diabetes; in cardiorenal disease the dyspnea can be *compared with exercise* dyspnea.

In making our observations, a respirator was used and by rebreathing the carbon dioxid content of the respired air was increased. The respiratory products were measured and the stimulating effect of carbon dioxid was noted. Respiration in most persons is increased so that pulmonary ventilation is doubled when the carbon dioxid reaches 4.5 or 5 per cent. In mild cardiac valvular disease, subjects behave in precisely the same way; in cardiorenal subjects, however, pulmonary ventilation is doubled when the carbon dioxid reaches 2.5 or 3 per cent. This difference in behavior is explainable on the basis that the reaction of the blood is more easily disturbed in cardiorenal disease on account of *the high acidity induced by the acidosis.* The experiments were further carried on to note the influence of alkalies in controlling the dyspnea.

Stokes-Adams Syndrome, with a Remarkable Delay in the A-V Conduction Time

Dr. W. S. Thayer, Baltimore: The woman on whom the observations were made was 50 or 55 years of age, the mother of several children. She had suffered with attacks of dyspnea for several years. After a series of attacks characterized by intermittent pulse, she became unconscious and the pulse became very slow. When I saw her she had a perfectly regular heart beat, rate 35 per minute. Examination with polygraph indicated that she was suffering from a total bradycardia with the A-V wave 0.7 second in duration. Electrocardiograms were made which upheld the suspicions excited by the polygraphic tracings, namely, that the heart was beating with one auricular to each ventricular contraction, and with the most remarkably prolonged p-r period of 0.68 second. After exercise, the pulse rate fell from 35 to 28 per minute, and by polygraphic tracings the A-V wave was now found to be 0.8 second, and later the A-V wave reached the unprecedented duration of nearly 0.9 second. It was desired to ascertain the effect of atropin, but the patient was hypersensitive to the drug, and its use had to be abandoned. There have been a number of similar seizures since, but the patient has utterly refused to allow further study. This case at first glance would seem to be one of ordinary heart block with dissociation; but on study it was found to be one of total bradycardia. So far as known, there is on record no other case with such a long pause between the auricular and ventricular contractions. Two polygraphic tracings taken six weeks apart with identical curves could hardly be a coincidence.

Present Status of the Electrocardiographic Method in Clinical Medicine

Dr. Alfred E. Cohn, New York: The electrocardiographic method has been used in clinical medicine for only ten years. It records the electrical discharges of the heart during its activity. The form of the curve remains constant through the greater portion of life. Any change in it represents a change in the heart or in its position. The normal curve depends on the orderly performance of four chief functions: (1) On the orderly spread of electrically excited states; (2) on the orderly sequence of auricles and ventricles; (3) on the orderly coordination of the muscular mass of each pair of cavities; (4) on the usual disposition and volume of the muscular mass of each pair of cavities. The abnormal electrocardiogram depends on a disturbance of one or more of these functions. Under the first head are grouped both auricular and ventricular extrasystoles, paroxysms of tachycardia, and changes in the T wave; under the second head, heart-blocks of various kinds; under the third head, the split P wave when there is auricular asynchronism in mitral stenosis, auricular fibrillation and flutter, ventricular asynchronism, and ventricular fibrillation; under the fourth head, the changes due to hypertrophy and dilatation and dextrocardia.

DISCUSSION OF SYMPOSIUM

Dr. L. F. Barker, Baltimore: The papers show very clearly the revolution in our ideas concerning the pathology of the circulatory apparatus. Electrocardiography is a method of investigation which has been so illuminating as almost to render the phlebogram and cardiogram merely historical. The arrhythmias by this method of study have been cleared up; the heart blocks are now well understood because of information derived from it; we have come also to understand auricular fibrillation—the 'delirium cordis" of older writers. By the method we have come to understand also that condition known as auricular flutter, the senile tachycardia, and we have had elucidated the controlling influence of digitalis on it. The electrocardiograph owes its greatest value perhaps to the fact that any unusual curve recorded by it from the human heart may be reproduced experimentally in animals, and thus our ideas may be cleared by demonstrable facts and we no longer need to depend on theory.

DR. JAMES B. HERRICK, Chicago: I wish to ask Dr. Cohn if there is any definite explanation of inversion of the T wave in Leads 1 and 2? There may often be seen such an inversion in various pathologic conditions, and its occurrence is usually regarded as of bad prognostic omen; why should this be so? I wish to ask also if the split P wave, seen in cases of mitral stenosis, might not at times be seen in curves from normal hearts? May it not be due to asynchronism of the ventricles?

DR. ALFRED E. COHN, New York: The T wave is sometimes inverted in Leads 1 and 2 without necessarily being very significant; but it is seen so regularly in so many very serious lesions that it is usually regarded as a bad prognostic sign. It may not invariably be a bad sign, however, because it may appear in a tracing from a case in which, if many tracings were taken, the majority would not show the inversion.

SYMPOSIUM ON THE DUODENUM

Physiology and Pathology of Duodenal Mucous Membrane

DR. THOMAS R. BROWN, Baltimore: The various problems which must be solved in studying the mucosa of the duodenum may be inferred by considering the events that here go on, depending on the simultaneous presence of three juices, all necessary and all secured by intricate reflex secretion. The extreme complexity of the physical and chemical events going on makes the problem important and difficult. Atony and spasm of the duodenum may both be functional. The hypothetic secretory function of the duodenum is explanatory of the stormy symptoms seen in high intestinal obstruction. The probable immediate cause of duodenal ulcer is the digestive action on the mucosa of trypsin and other proteolytic ferments; but what accident befalls the mucosa to account for this invasion? This has not been demonstrated. Hyperacidity may account for the accident or the action of some vagatonin in psychoneurotic individuals; or some infectious process may underly the event.

Use of the Duodenal Tube for Diagnosis and Treatment

DR. FRANKLIN W. WHITE, Boston: The clinical use of the duodenal tube (introduced by Einhorn and by Gross in 1909-1910) has proved its value in a limited field. I used the tube in eighty-six cases, in sixty-six for diagnosis; in twenty for treatment. A fluoroscopic study of the technic of the introduction of the duodenal tube showed that by placing the fasting patient successively in simple postures, the tube may be introduced into the duodenum within half an hour in a majority of cases in which organic stenosis is not present. Spasm of the pylorus, and atonic and hook-shaped stomachs may delay the tube. A heavy (Gross) tube tip enters the duodenum more rapidly than a light (Einhorn) tube tip. A small tube No. 8 French with a heavy tip of at least 100 grains' weight (Palefski) is best of all for diagnostic work. It is not difficult to tell the position of the end of the tube. It is as safe as an ordinary stomach tube.

In diagnosis, examination of the duodenal contents was most useful in diseases of the pancreas and in cases of chronic jaundice. It is the only method of directly obtaining the secretions of the pancreas and liver. There is considerable normal variation in the pancreatic ferments; only absence or marked diminution has much value in diagnosis. Examination of the feces in some cases was almost equally valuable and simpler; in others the examination of the duodenal contents was much more valuable. In treatment the duodenal tube (Einhorn) was useful in a limited group of cases of peptic ulcer. (It was used only in cases without organic obstruction and in cases resisting ordinary medical treatment.) It may be used to improve the patient's condition before operation, in ptosis and atony with delay in emptying the stomach and vomiting, and it has considerable value in cases of persistent vomiting of nervous and toxic type. Here an unusually long tube is desirable to prevent regurgitation into the stomach. It was used in two cases of cancer of the esophagus (stomach feeding). Almost every case was improved by duodenal feeding, and in a considerable number the symptoms stopped. It is superior to rectal feeding, as patients keep their weight or gain. A vacuum bottle as reservoir and the Murphy drop method is preferred to a syringe for introducing food.

8 Behavior Chart in Mental Diseases. E. J. Kempf, Baltimore.
9 *Colloidal Gold and Other Tests Applied to Spinal Fluid in Psychiatry. P. G. Weston, I. A. Darling and P. B. Newcomb, Warren, Pa.

4. **Typhoid with Permanent Memory Defect.**—One of Henderson's patients had typhoid in 1910, followed by an indifferent placid state, with outbreaks of irritability, and a marked persistent memory reduction for recent events. The other patient had typhoid in 1903, followed by a marked defect in memory for recent events, which has been persistent, and followed later by an unstable, variable, emotional condition with vague ideas of persecution.

6. **Thymus and Pituitary in Dementia Praecox.**—In a group of cases of dementia praecox examined by Ludlum and Corson-White, Abderhalden reactions were obtained in some instances to testicle and pancreas; and in others to testicle and thyroid; while in still others no reaction could be secured. In the individuals that gave the reactions to testicle and pancreas, there were observed physiologic symptoms of the same type as those found in animals from which the thymus had been removed. In examining the blood of animals whose thymus had been removed, the same reactions were obtained as in the cases of a certain group of patients, indicating that in this group there exists a disease entity. With regard to the pituitary, there were a considerable number of cases with the symptoms of dyspituitarism that improved with pituitary extract. There were also a group of cases of hyperpituitarism that improved with the opposite organic extract, which is the Brown-Séquard fluid.

From a comparatively large number of examinations in cases of pregnancy, cancer, sarcoma, mental disease and experimental animals (examinations carefully repeated and doubly controlled), the authors feel that the Abderhalden reaction is specific; that is, that it represents a definite specific phenomenon. Whatever the ultimate explanation of the phenomenon may be, whether as Abderhalden suggests, it is due to the presence of a specific protective ferment, or, as Bronfenbrenner and Schwartz suggest, that it is an autodigestion of the serum by the specific removal of a normal inhibiting substance, probably the antitrypsin allowing the normal protease to act—it is the expression of a specific phenomenon.

7. **Forms of Manic-Depressive Insanity.**—The essence of the manic-depressive reactions, according to Singer, is the occurrence of some appropriate affective attitude of the organism as a whole which is of purposeful character, abnormal because of its severity and duration and because there is no apparent external cause of its adoption. The so-called mixed states and atypical forms are not mixtures simply of certain traits, but represent affective oscillations colored by peculiarities in the make-up of the individual patient. Such modes of adjustment must be carefully studied and weighed in rendering a prognosis in any individual case.

9. **Tests Applied to Spinal Fluid in Psychiatry.**—This report is based on a study of 198 individuals suffering from different psychoses. In all 239 separate punctures and examinations of the spinal fluid, which, in addition to the "goldsol" test, were also subjected to the scrutiny of the Wassermann reaction, estimation of the globulin content by the Noguchi butyric acid method, cell count and volumetric approximation of albumin. In the cases (3) diagnosed clinically as cerebrospinal syphilis the Wassermann reaction on the spinal fluid was always positive and the colloidal gold test showed a reaction in the paretic zone. In paresis (34 cases) the colloidal gold test was always found positive in cases in which the spinal fluid showed a similar reaction to the Wassermann test, in addition to which one instance is noted in which the fluid Wassermann was negative, but a reaction in the luetic zone was obtained by the gold solution. In dementia praecox (98 cases), manic-depressive insanity (25 cases), arteriosclerotic dementia (17 cases), and epilepsy (12 cases), there was no positive Wassermann reactions on the fluid, and likewise no response to the gold solution in the typical "paretic zone." However, the latter reagent did furnish, in 8 cases of the 152 examined, a reaction within the minor limits of the "luetic zone."

In the unclassified psychoses (9 cases), the colloidal gold and the Wassermann reactions on the fluid ran a parallel course, except in one case, which showed a negative response to the Wassermann test on the fluid, but gave a gold reaction in the "paretic zone." This instance is clinically a possible case of paresis. The opinion is given by the authors that the colloidal gold reaction forms a useful adjuvant to the Wassermann, is apparently as reliable, and, in some instances, by reason of positive response in the absence of the Wassermann in clinically luetic cases, has seemed to point toward the possible appearance of a later positive Wassermann in the suspected individuals.

17. **Operative Treatment of Arterial Thrombosis and Embolism.**—In one case cited by Stewart a diagnosis was made of an embolus in the abdominal aorta at the origin of the left common iliac artery. Pulsation of the abdominal aorta could be made out by palpation. Pulsation could not be felt in the external iliacs, or in any of the arteries in the lower limbs. The right foot was black and shriveled, the lower two-thirds of the right leg purplish, with loosening of the epidermis and bleb formation. The left leg was painful, tender, useless, warm (because of the presence of external heat) and pale, except over an indurated area, about 2 inches in diameter, just external to the middle of the tibia, in which the skin was reddened and edematous.

The abdomen was opened in the median line below the umbilicus, the small intestine segregated in the right side of the abdomen, and the sigmoid pressed to the left. The iliacs were motionless; the aorta pulsated to a point near the bifurcation, at which point it was hard. The posterior parietal peritoneum was incised, and a silk ligature passed beneath the aorta at a point 1½ inches above the bifurcation. This ligature was not tied, but it was placed so that it could be tied in the event of bleeding that could not be controlled otherwise. While an assistant compressed the aorta with a finger, a longitudinal incision extending upward from the bifurcation for three-fourths of an inch, was made in the anterior wall of the aorta. After removing, in several pieces, a dark friable clot, evidently of recent formation, which lay beneath the incision and protruded into the left common iliac artery, the embolus itself was uncovered, and easily forced through the wound by pressure, from below upward, on the right common iliac artery into the orifice of which the lower end of the embolus had been driven. There were apparently no firm adhesions between the obstructing mass and the intima, which appeared to be smooth and undamaged.

After milking several more small fragments of clot from the left common iliac, pressure on the aorta was relaxed for an instant, in order to wash any remaining coagula through the wound, and the aorta closed with a continuous through-and-through silk suture, over which a second continuous suture, including the outer coats only, were inserted. The posterior parietal peritoneum was drawn together with a continuous suture of catgut, the abdominal wall with interrupted stitches of silkworm-gut. The operation, which lasted about an hour, had little immediate effect on the patient's general condition. On the third day after the operation death occurred from cardiac weakness and pulmonary edema. A necropsy could not be obtained.

18. **Gallstones.**—A study of 400 cases of gallstones entering the surgical wards of the Boston City Hospital in the years 1907 to 1913 (six years) was made by Hubbard and Kimpton. Only such cases were used in this study in which stones were found at operation, 226 cases, 55 males and 182 females. Pain of severe type was practically always the prominent symptom, occurring in 212 cases. The second prominent symptom was vomiting, present in 137 cases, or 62 per cent., varying from mild to severe, persistent and most distressing. Jaundice varying from a yellow discoloration in the eyes to a definite yellow tinge to the whole body is mentioned in 107 cases, or 48 per cent. The site of the stones is of special interest in these cases of jaundice. Of the 107 jaundiced persons 70 had stones in the gallbladder only; 25 had stones in the common duct only or in addition to stones in other portions of the biliary tract; 9 in the cystic duct alone, or in conjunction with stones elsewhere, and in 3 the stones are described as being in the "ducts." Chills occurred only 9 times.

The character of the stools was mentioned in but a few of the cases, in 14 clay or white, in 2 light colored. A mass in the abdomen was present in 49 cases with a questionable mass in 6 additional. Pus was present in the gallbladder in 28 cases. It was found in both contracted and distended bladders. A contracted bladder occurred in connection with a stone in the common duct more frequently than a distended bladder. Cholecystostomy was performed in 177 and cholecystectomy, complete or partial, in 24 cases. Pulmonary complications developed in 14 cases, and in a majority of these caused death. Thirty-one patients died in the hospital as a result, or in spite of operation. The end-results, not including those patients who died in the hospital, have been learned in 91 cases. Seventy-four, or 81 per cent., consider themselves well, cured by the original operation. Of this number, 5 qualify this statement by saying that they still have some indigestion. Four patients are having trouble, not apparently due to gallbladder disease. Three still have attacks of pain, etc., suggestive of gallstones, and one is "not well."

20. **Gastro-Enterostomy in Ulcers.**—According to Martin and Carroll, it can be shown roentgenographically that in man, as well as experimentally in animals, a patent pylorus tends to functionate notwithstanding the presence of a patent stoma; that gastric contents will leave via the stoma, and at first in large quantity, but that it is not a fact that the egress continues rapidly later.

22. **Cystic Dilatation of Vermiform Appendix.**—This is a rare form of appendix disease, available postmortem records showing it to be present in about 0.2 per cent. of cases. It is usually symptomless and benign, but may, on rupture, produce pseudomyxoma peritonei in every way similar to that of ovarian cyst origin.

24. Abstracted in The Journal, Jan. 23, 1915, p. 365.

25. **Tongue-Depressor Gastro-Enterostomy Clamp.**—Gibson uses three small pieces of wood, the ordinary wooden tongue-depressors, bound together by any suitable method, such as a strong artery clamp, or, if more convenient, a sterile rubber band. The tongue-depressors might be replaced by strips of cigar boxes. Both in experimental and clinical work, it has proved much more satisfactory than the Roosevelt, Bartlett and other clamps used for this purpose. Gibson has found it particularly satisfactory in doing a gastro-enterostomy, when it is desired to release the clamp in putting in the last mucous muscular suture and the final peritoneal suture. Removing the rubber band allowed the tongue-depressors to fall apart without further manipulation. By this method injury to the viscera is less likely to be produced. Two gastro-enterostomies and one entero-anastomosis have been successfully done with the aid of these clamps.

26. **Prevention of Keloids in Scars.**—A young woman consulted Freeman regarding the removal of a disfiguring scar resulting from an operation for tuberculous lymph nodes of the left side of the neck. It extended from the mastoid to the center of the clavicle and was as wide and as thick as one's thumb. It was fiery red and formed a conspicuous and mortifying deformity, as it stretched across the neck like a great "flying buttress." A strip of fascia lata was procured from the thigh, long enough to reach from the mastoid almost to the clavicle, with the head in the median position, and about as broad as one's finger. After thoroughly extirpating the scar and undermining the edges of the wound, the strip was spread lengthwise beneath the incision. It was then fastened to the under surface of the skin and fascia on one side, and to the deeper tissues on the other side, with a few sutures of fine catgut, thus permitting the union above it of the integument and cervical fascia without danger of displacement. Primary union was obtained. Posterior to the longer scar described above was a much shorter one, which was also hypertrophied and red. This was likewise excised, but for various reasons was not underlined with fascia lata, although the deep fascia was carefully sutured. Hence this second scar became a sort of "control experiment."

At the end of over twelve months the results of the procedure are as follows: When an attempt is made to incline the head to the opposite side, this movement is checked by the strip of fascia lata, which stands out plainly beneath the skin. This does not inconvenience the patient, because the same check was produced to even a greater extent by the false keloid. There is absolutely no pull on the new scar, which is soft and freely movable on the surface of the underlying graft. There is little tendency to hypertrophy or redness, except near the clavicle, to which the fascial strip did not quite extend. In other words, the new scar is relatively inconspicuous and "normal." The smaller posterior scar, the "control experiment," which was not underlined, has become markedly red and elevated, in spite of its being relieved from a certain amount of strain by the anterior fascial graft; while the longitudinal scar on the thigh from which the graft was obtained is fiery red and almost as broad and thick as one's little finger. In a second case the disfigurement was not so great as in the preceding case, but it was sufficient to justify an energetic attempt at its removal. The result, at the end of four months, is eminently satisfactory, the scar being small, soft, not red and freely movable over the fascial graft.

28. **Amputations of Leg.**—In cases of amputation through the upper two-thirds of the leg, Finochietto says, examinations, operations and dressings should be done while the patient is in the ventral decubitus. All classes of anesthetics can be administered and will be perfectly tolerated in that position. While in this position flaps of any form can be raised and one may employ at will subperiosteal, periosteal, anaperiosteal and osteoplastic methods. Any method of amputation can be performed more easily while the patient is in the ventral decubitus. Equally well, in the same position, any condition which involves all or a greater part of the leg circumference, as ulcer, lymphangiomata, cirsoid aneurysms, etc., may be examined and operated.

48 *Some Sequelae of Antityphoid Inoculation. W. Boyd, Winnipeg, Manitoba.
49 Juvenile Delinquency. G. S. Mundie, Victoria, B. C.

47. **Uterine Hemorrhage at and After Menopause.**—Cleland summarizes his paper as follows: The menopause is probably induced by retrogressive changes in the ovary. The

menopause is subsidence of the flow of blood, an increase in the flow is always pathologic. The menopause may occur during a period of thirty years or more. A local examination should always be made in cases in which hemorrhage occurs near the menopause. Professional and public education regarding the early symptoms of cancer of the uterus is necessary. In severe cases of uterine hemorrhage which have resisted all medicinal treatment and in which the patient is becoming progressively worse, hysterectomy is indicated. There seems to be no connection between hyperplasia and hypertrophy of the endometrium and hemorrhage from the uterus. At or near the menopause the curet is of little service except for diagnostic purposes. No palliative measures should be tried till malignant disease is excluded. General conditions may be the cause of hemorrhage, and syphilis should not be overlooked. Organotherapy is of little value in hemorrhage at or after the menopause. Blood transfusion is a possibility in treatment of severe cases,.

48. **Sequelae of Antityphoid Inoculation.**—The effects of prophylactic inoculation were observed by Boyd on the 18,000 men composing the North Midland Division of the Territorial Force. In quite a number of cases definite evidence was observed of a considerable increase of intestinal activity. In one case inoculation bore a close causal relationship to an attack of typhoid. In four cases jaundice developed a few days after inoculation. In two cases inoculation was closely followed by an attack of pneumonia. Three cases of severe urticaria came under Boyd's observation. In one of these the color was of a remarkably vivid hue; it was as if the patient had been steeped in some anilin dye, such as eosin. In no case did the condition last for more than forty-eight hours. None of the cases showed any rise of temperature. The author concludes that in the great majority of cases inoculation is a harmless procedure, involving at the most a certain degree of temporary discomfort, and those constitutional symptoms comprised under the term "inoculation fever." In a few cases the sequelae are of a more serious character, and in some instances inoculation may be followed by such conditions as pneumonia, appendicitis (two cases) and severe gastro-intestinal catarrh.

74 *Some Vasomotor Reactions of Liver, with Special Reference to Presence of Vasomotor Nerves to Portal Vein. C. W. Edmunds, Ann Arbor, Mich.
75 *Demonstration by Use of Arterial Rings of Inhibitory Action of Certain Drugs on Vasoconstriction Produced by Epinephrin. D. I. Macht, Baltimore.

73. **Toxicity of Rattlesnake Serum.**—According to Welker and Marshall, rattlesnake venom injected intramuscularly into the same rattlesnake or into another rattlesnake is not toxic. Injected intraperitoneally into guinea-pigs and intramuscularly into pigeons, it appears to be less toxic than rabbit serum. Captivity of the rattlesnake seems to produce an abnormal condition of the blood that is unfavorable to blood clotting. The bile of the rattlesnake is not highly toxic for pigeons, nor has it any antitoxic action for rattlesnake venom.

74. **Some Vasomotor Reactions of Liver.**—It was noted by Edmunds that under the action of epinephrin the liver volume changes are not the same in all animals, even in those of the same species. In the dog the usual effect of the injection of epinephrin is a constriction of the liver which continues during the time that the general blood pressure is reaching its maximum and returning to normal again. In the cat the usual type encountered is an increase in volume dependent on the increased efficiency of the heart. Variations from both types are frequently seen. When the hepatic artery is tied, all the types resolve into one. In this type there is no marked change in volume during the early portion of the curve, but later there is a marked increase. This increase is the result of the backing back of the blood in the vena cava, and it is therefore entirely passive. Injected into the intact animal epinephrin gives no proof of the presence of vasomotor nerves in the portal vein. These, however, can be demonstrated by the perfusion of the portal system with epinephrin solutions and by the action of these solutions on isolated pieces of portal vein, and finally by the study of the volume changes in the liver in relation to the vena cava and portal pressures when the splanchnic nerves are stimulated.

75. **Action of Certain Drugs on Vasoconstriction.**—Macht found that Dale's vasomotor paradox can be demonstrated in vitro or outside the body in a simple and effective manner, by the use of excised arteries. One or more rings of a freshly excised artery are suspended in a small glass chamber filled with warm Locke's solution at the temperature of 37 C. (98.6 F.), through which a constant stream of oxygen is kept bubbling. One end of the preparation is fixed to the bottom of the chamber, while the other is connected to the short arm of a lever, the long arm carrying a point for recording on a very slowly moving kymograph. The glass chamber is immersed in a water bath or a jacket for regulating the temperature. The temperature and flow of oxygen must be kept very constant. When the artery is excised it is in a state of permanent contracture or "tonus," which tonus must be overcome before its reaction to drugs can be studied. This is done by a method of so-called "weighting," originally introduced by O. B. Meyer, and was described by Voegtlin and Macht in their work on the coronary and pulmonary arteries.

When the tonus of the artery has been overcome and the lever is writing at a constant level, small quantities of ergotoxin solution are introduced into the small chamber. The effect of this drug is usually to cause a moderate but long lasting contraction of the arterial rings. If now the Locke solution is quickly removed, and fresh solution of epinephrin in warm Locke (37 C.) is introduced in its place, or if some strong solution of epinephrin is mixed directly with the original Locke solution, instead of the ordinary sharp rise due to epinephrin, as seen in normal rings, no constriction occurs, and indeed very often there is a relaxation noted. Macht says that the original contraction of the arterial ring is due to the direct action of the ergotoxin on the artery. While causing a constriction of the ring, the ergotoxin at the same time paralyzes the motor endings in the vessel wall, giving an exactly similar paradoxical reaction to epinephrin as that observed in blood-pressure experiments in the intact animal.

99 *Homograde Thermometer. F. E. Aspinwall, La Grange, Ky.

94. **Diagnosis and Treatment of Cancer of Stomach.**—Meyers suggests that if there are any antibodies or special resistance passed from the parents to the children, the offspring may benefit in the way of immunity to disease, and thus the race is guarded. This is not so in cancer, for even if the host of cancer does elaborate any antibodies against his or her disease, yet through age or shortened life he or she does not transmit them to any descendants. And it may be for this reason that cancer is on the increase because we have more people in the world today only a few of whom can possibly be the sons or daughters of cancer fathers or mothers. If the cancer patients could produce or bear children there might come a time, perhaps very distant, when the human being would develop more resistance against cancer than he now possesses. As it is now, cancer cases serve no general purpose of immunization. In the face of a situation so serious and baffling it would seem advisable to Meyers to urge men and women with cancer to produce children before they die. If they do not marry it would be well for the state to sanction and provide for marriage so that all cancer material could be employed to produce children who might be immune through transmitted resistance.

99. **Homograde Thermometer.**—In the Homograde thermometer the normal blood heat at or near the surface of the body in which sensation mostly exists is the unit of value, and every degree in the scale equals 1 per cent. of that unit. The scale begins with O at the freezing point, 270 represents the boiling point of water, and 100 the normal blood heat within the radius of sensation. In the Homograde scale 100 represents the human normal and all variations therefrom are expressed in percentages of that normal; 95 H. expresses 95 per cent. of that heat, a 5 per cent. deficiency; 105 H. expresses a 5 per cent. increase of heat, a moderate and usually not dangerous fever, while 110 H. expresses a 10 per cent. increase of heat, which is high and proportionately dangerous. To change Fahrenheit figures to Homograde find the exact number of degrees above or below freezing and increase that number one-half. The result will be the Homograde equivalent. Throughout the Homograde scale there are exactly 3 degrees instead of 2 degrees in the Fahrenheit scale. The shorter degrees of the Homograde thermometer necessitate a less frequent use of fractions.

126 Congenital Diverticulum of Urinary Bladder in Infants and Children. J. M. Wallfield, New York.
127 Water as Physiologic Tonic. A. C. Geyser, New York.

119. **Whooping Cough.**—Pertussis stock vaccines as prepared by the New York Health Department Bureau of Laboratories, according to Luttinger, seem to have a prophylactic value when given in high doses. In the treatment of pertussis, these vaccines seem to have shortened the duration and severity of the paroxysmal stage; the average duration of the whoop being twenty-five days, compared to forty days of those treated with drugs.

125. **Eczema Cured by Reduction of Carbohydrates.**—Concluding that the sugar must be at fault in his case, Sturtevant omitted all carbohydrates from the formula. Improvement was immediate; the next day the temperature fell, and daily the eczema could be seen to improve. In six days the face was entirely clear. The baby lost about 8 ounces in weight, however, in the six days. The addition of a half dram of dextramaltose to each feeding (6 ounces every fourth hour) was followed by a regain of the weight lost, but no more. After a few days of stationary weight, the sugar was increased suddenly to 5 per cent. There was an immediate

return of the eczema, more mucus in the stools, and a slight but persistent elevation of temperature again, Sturtevant omitted all sugar. As before, all symptoms disappeared in a few days. Beginning now with small additions of sugar each few days, gradually developing an increased tolerance for this food element, he succeeded in getting small gains in weight and discharged the patient apparently cured. Observation in the dispensary and social service department recorded continued improvement.

136 As Surgical Assistant is Anesthetist Sufficiently Trained? S. F. Wiltsie, Seattle.

131. **Effusion into Bowel Wall.**—The four cases cited by Riggs in their history resemble the symptoms of appendix trouble more or less acute. The central abdominal pain, shifting to the right lower quadrant, with tenderness on pressure over this area, the slight rigidity of the right rectus, vomiting, temperature ranging from 99 to 103, make the clinical picture of inflammation of the appendix. The doughy mass felt in several cases, gave the impression of a possible abscess. The pathology is more or less uncertain. The site of the lesion is constant, occurring at the lower few inches of the ileum and sometimes involving a contiguous portion of the cecum. It is to be noted that this area is supplied by the ileocolic artery. The congestion varied from a slight reddening to a dark red color. There was great thickening of the bowel wall and of the mesentery. This is not of the edematous type which pits on pressure, but has more of the brawny feel of an inflammatory infiltration. The area affected is usually quite sharply defined and does not shade gradually to the normal. In one case there were petechial hemorrhages in the mucous membrane of the appendix, while in another there was apparently blood in the stool. A bacteriologic examination in the only appendix involved gave only *B. coli* and pyocyaneus.

Riggs believes that this may be regarded as a manifestation of a toxemic condition which has for its outward sign erythema, urticaria, angioneurotic edema and purpura. The abdominal pain, the vomiting, the temperature and the site of the lesion correspond to the description given by Henoch of abdominal purpura. In the cases Riggs reports, the question of hemorrhage is almost negligible. One had petechial hemorrhages, another presumably had blood in the stool, but there was no marked hemorrhage from any part of the alimentary tract. The other case showed absolutely no sign whatever of a purpuric nature.

4 *Case of Myelitis in Child. H. T. Ashby.

4. **Myelitis in Child.**—The patient was a boy, aged 5½ years, who first complained of vague pains in the chest. The parents also noticed that he was slowly losing the use of his legs. The family history was good, and previous to the onset of the illness he had always been healthy. He had not had any of the infectious fevers. When sent by his physician there was complete paralysis of both legs and back, with anesthesia extending from the toes up to a line drawn round the chest just below the nipples. The knee jerks were much exaggerated, and there was a Babinski sign present on both sides. The abdominal reflexes were absent. There was no optic neuritis and no impairment of the mental power. The upper extremities and neck were unaffected. The urine was normal, but continually dribbling away, and there was also incontinence of feces during his stay in the hospital, and up to the time of death he complained of vague pains in the chest and in the upper abdomen, but his general condition remained the same till just before he died.

There was only a slight rise of temperature on and off throughout the illness, but just before death he had hyperpyrexia. He had a small bed-sore on admission to the hospital, which, however, soon healed. The heart and lungs were normal. After three weeks, the anesthesia, which had remained at the same level, began to increase upward and he became rapidly worse, no doubt due to the vital centers becoming affected. There was no improvement with potassium iodid, no family history of syphilis, and the Wassermann test was negative. There was no spinal caries nor injury, and the case was quite unlike anterior poliomyelitis or a spinal growth. The disease seemed to spread up the cord quickly at first, became stationary for a time, and then advanced till the vital centers were affected.

12. **Decortication for Traumatic Empyema.**—For recent cases of empyema the essential thing, Spencer says, is to sponge the cavity free from fibrin and pus, and then by the finger, aided by sponges on holders, to seize portions of the capsule with forceps in order to free the lung. This can safely be done if the patient is given nitrous oxid gas with oxygen or air; as the lung is being freed a little ether will induce cough with which the lung will expand. The difficulty in children may be the occurrence of bronchopneumonia with the empyema. Then, after the pleural cavity has been cleared, the lung may be found free, but it cannot expand owing to consolidation. If the base of the lung is then drawn into the wound and fixed there by suture with a tube beside it leading into the cavity, healing will soon occur.

19. **Ileus Duplex.**—Peritonitis of the serous surface of the intestine, when it reaches a certain degree, is accompanied by complete paralysis of the involved segment of intestine. General peritonitis means general paralysis of the intestine, and is accordingly not amenable to surgical treatment. But if the peritonitis is partial though unlimited by any adhesion barrier, certain segments only of the intestine are paralyzed. If the paralyzed segments can be thrown out of circuit by surgical measures, recovery is in such cases possible and even likely. Unfortunately, in these cases the surgeon's hand has been paralyzed by a facile assumption, based on the general abdominal distention, that general peritonitis is present. The observations Handley has made in the operating room and the successful results of his cases show conclusively that septic ileus of pelvic origin is not accompanied by general peritonitis when it first comes under observation, and that it is perfectly amenable to surgical treatment, subject to a clear recognition of the fact that two segments of the bowel are involved, and that accordingly two obstructions require to be circumvented.

22. **Theory of Telephone Probe.**—This instrument was designed for the location of bullets and other foreign metallic matter within the human body. It consists essentially of a telephone receiver, one terminal of which is electrically connected with the skin of the patient by means of a flat electrode covered with wet cloth, while the other terminal is connected with a metallic probe. A dry battery may or may not be inserted in series with the telephone. The probe is introduced along the track of the bullet, and on contact being made with the latter a sound is produced in the telephone. The instrument is of real value only when the ordinary methods of detection are of no avail and when the Roentgen ray, if obtainable, is deceptive.

25. **Arteriovenous Aneurysm.**—Osler agrees with the conclusion arrived at by Subbotich, senior surgeon of the Belgrade State Hospital, from his experience in the Balkan War, "that arteriovenous aneurysms should be operated on, as they offer small prospect of spontaneous cure, although they often remain stationary for a long time and cause relatively little trouble." It is suggested that the question is largely one of situation and technic. As the cases reported by him indicate, even with the lesion of the axillary and subclavian vessels good health may be maintained for years without any serious trouble, but there are always risks, particularly of thrombus formation in the distended veins, and even after thirty or forty years serious trouble may arise. Urgency is greater in the case of the lower limbs, and it would be much safer to operate before the venous engorgement becomes excessive. Osler emphasizes the fact that up-to-date vascular surgery cannot be done in a hospital in which the younger surgeons have not full opportunities to experiment on animals, because the extraordinarily delicate technic of vascular suturing is an art acquired only after much practice.

26. **Etiology of Rickets.**—Examination of his results, Findlay says, shows very definitely that the disease is proportionate to the amount of air space allowed to the child, and that as this diminishes in amount the incidence of the disease rapidly increases. Probably the want of sufficient fresh air acts in a twofold manner. In the first place, the absence of pure air will act as a sedative and tend to make the child less inclined for exercise. If a child is confined to the house it is more easily tired, is less active, and wishes to go to bed earlier, so that the living in overcrowded rooms acts just in an opposite manner to taking the child out. Again, it is not unlikely that in overcrowded houses the amount of work that devolves on the mother will hinder her from attending properly to the child.

Closely allied to the above is the amount of time that the child spends in the open air. In the larger proportion of the cases the mother confesses to not taking the child out at all. These two factors, confinement and deficient fresh air, act by making the child more lethargic and less inclined to exercise itself, although it is quite possible that deficient oxygenation of the blood itself helps toward the production of the special rachitic metabolic error. The results which Findlay has obtained in the treatment of the disease with massage, passive movement and electricity are, he believes, strongly confirmatory of the view that deficient exercise engenders the condition. So far as his experience goes, no variety of dietetic or medicinal treatment brings about the same rapid and complete cure. The children are encouraged to walk, and as yet Findlay has not seen any bad effects follow such practice.

In view of the effect of deficient exercise on the calcium retention, the influence of confinement in the production of human and experimental rickets, and the frequency with which the disease is encountered in overcrowded houses, Findlay considered it not unlikely that rickets would be exceedingly prevalent in those parts of the world in which the people were confined in badly ventilated houses and from which sunlight was absent for long periods of the year. After a fairly extensive search through the diaries and journals of travelers in Iceland, Greenland and Alaska, parts of the world in which the winters are long and dark and in which the houses are badly ventilated and devoid of all sanitary conveniences, houses in which many people are huddled together for weeks at a time, he has not come across a single suggestion that rickets is ever encountered.

42 Fatal Gastro-Intestinal Hemorrhage in Newborn. S. Sheill.

37. **Duodenum in Diabetes Mellitus.**—In nine consecutive patients with severe diabetes mellitus observed by Mutch, the mean vertical length of the duodenum was 3⅓ vertebra, the extremes being 3 and 3½ inches. Considering adults only, the average length was 4⅘ inches, and the extremes 4½ and 5½ inches, respectively. These figures represent a very great enlargement of the organ; in fact, one patient's duodenum was twice as long as that of a healthy adult and was increased in caliber also, and on examination after death, the walls were seen to share the same change, being thick and fleshy, and of a somewhat milky appearance. Mutch says that the same alterations in structure can be traced in the upper portions of the jejunum.

This enlargement is also invariably associated with ileal or colonic stasis, and in some patients delay is so extreme, and the consequent modification of, the lower bowel so advanced, that there is no doubt in Mutch's mind but that alimentary stasis preceded the onset of diabetes; as, for example, in the case of one patient whose duodenum showed strong antiperistaltic movements. The duodenal dilatation of such patients might reasonably be ascribed to the factors which produce this abnormality in simple intestinal stasis. In the majority of cases, however, the increase in size of the upper part of the small intestine is the predominant change in the alnimentary canal, while lower bowel delay and duodenal regurgitation, although present, are not sufficiently pronounced to account for the enlargement. Fecal accumulation is evidently a common concomitant of diabetes mellitus, but not the sole determining factor, although it may be a predisposing cause. That ileal stasis plays an important part in the disease, Mutch believes, is clearly shown by an analysis he made in which the patients are classified according to the severity of their acidosis. The intensity of the disease was directly proportional to the degree of ileal stasis.

Almost all diabetic patients excrete indoxyl indolacetic acid, and parahydroxyphenylacetic acid in their urine, in varying proportions. In constipated subjects, these substances arise either directly or indirectly from the action of *B. coli* on tryptophan and tyrosin in the small intestines, and the amounts excreted serve as an index of the extent to which the ileum is infected with coliform organisms. In diabetes mellitus, the excretion of these bodies does not bear any obvious relationship to the severity of the disease, from which fact it may be inferred that the gravity of the prognosis in diabetics, with marked ileal delay, depends on some condition other than the coincident infection of the small intestine with coliform organisms. A profuse growth of streptococcus brevis was obtained from the duodenum of a boy with severe diabetes mellitus. The suggested explanation of these phenomena is that chronic duodenitis is the determining factor in the production of diabetes mellitus, and that ileal delay increases the severity of the disease by causing stagnation in the duodenum.

40. **Cancer of Breast.**—Howard's youngest patient was 23. Eighty-six of the patients were over 35 years of age. No definite connection between cancer and marriage, pregnancy or suckling could be made out, but the cases with the shortest histories were, on the whole, seen in the unmarried. Three cases had had abscesses in the breasts some years before the appearance of the cancer. In none of the 100 cases was there a definite history of injury preceding the appearance of the tumor. In sixty-seven of the 100 cases the lump in the breast was discovered by accident. In four cases the patient came for advice for a discharge from the nipple. Three patients suffered from spontaneous fracture, due to secondary cancer in the bones; but all three had been aware of a lump in the breast for some months, and had not sought advice because it was painless. The mortality for the 100 cases is three.

One patient had a goiter and did not recover consciousness. The second, an elderly lady, died quite suddenly after the stitches were removed, and was found on postmortem examination to have extreme fatty degeneration of the heart. The third was a woman of 42, who died suddenly of pulmonary embolism, while having tea with her friends on the seventh day after the operation. Out of the 100 cases, Howard has so far performed eleven operations for recurrence, five locally in the skin, four in the supraclavicular glands and two in the opposite breast. Recurrence in the lungs has been seen five times, the patient first complaining of a dry cough and then developing signs of solidification of the lungs or fluid in the pleura. In one case there was recurrence in the dorsal spine, but Howard has not seen any other case of recurrence in the bones. In two cases recurrence in the skin occurred five years after the original operation, but in one of these the secondary growth was removed, and at the time of writing there is no further recurrence.

Howard's experience of radium is limited to two cases, both of which were inoperable. Neither received the slightest benefit from the treatment. Eight cases of recurrence were treated by Roentgen rays, and temporary improvement has resulted in several of them. In one case a large mass appeared in the opposite breast after removal of one for cancer. This mass had all the clinical characters of a cancer. It completely disappeared under Roentgen-ray treatment, and later the patient died with recurrence in the thorax.

47 *The Symptoms Characteristic of Tricuspid Insufficiency; Especially the Ventricular Venous Pulse. C. Esmein.

43. **"Curable" Meningeal Hemorrhage in the Young.**—Cordier discusses the history of the so-called spontaneous and curable hemorrhage in the meninges and its connection with eventual acute hemorrhagic encephalitis, its nature and its outcome. The afterhistory of but few of the patients is known, and a case in his own experience suggests that the prognosis is graver than is generally assumed. In his case a man of 22 was treated at the hospital for supposed acute meningitis following influenza. He had previously been healthy, but his wife was a consumptive. Lumbar puncture released hemorrhagic fluid under high pressure, the symptoms gradually subsided and the patient seemed quite cured. Ten months later meningeal symptoms developed again, extremely severe, and soon fatal. Six illustrations are given of the findings in the brain. They indicated a hemorrhagic encephalitis, and Cordier is convinced that this was directly connected with the first meningeal hemorrhage. The latter must be regarded as the subarachnoid localization of some toxi-infection or latent unrecognized intoxication. This probably is the condition in all such cases hitherto regarded as spontaneous and curable. There is probably always some meningo-encephalitis, but the brain is affected so slightly that the symptoms from this escape attention. Sooner or later, however, the latent toxi-infection may flare up and the point of lessened resistance in the brain bear the brunt of it.

47. **Symptoms of Tricuspid Insufficiency.**—Esmein's long critical study of this subject has demonstrated, he says, that pulsation in the jugular veins does not always accompany tricuspid insufficiency and may, in rare instances, occur without it. Pulsation of the liver is still rarer, but when it is noted tricuspid regurgitation is practically certain.

49 Slight Degrees of Pulsus Alternans Revealed by Auscultation of the Arteries. L. Bard.

48. **Auscultation of the Arteries.**—Bard has been studying the murmur in an artery as he slightly obstructed it by pres-

sure with a stethoscope. The murmurs vary widely in intensity and in the facility with which they can be induced. Greater precision is attained by partially obstructing the circulation with a sphygmograph cuff and ausculting below with a phonendoscope. Sounds are heard constantly in the artery, varying in intensity and tone; murmurs also are constant, but they are very faint with a normal circulation. With pathologic conditions in the circulation, the murmurs are extremely intense or entirely imperceptible. He says that analyzing the mechanism of the murmur reveals that it is dependent on the emptiness of the peripheral segment of the artery below the constriction. Whether the artery in this segment is empty depends in turn on whether the blood from it has passed on normally into the capillaries or whether the blood has encountered resistance and is thus unable to flow off out of this segment. Other factors may contribute, but this is the instructive factor. The most pronounced murmurs were in certain cases of aortic insufficiency of endocarditic origin, while no murmurs were perceptible in the cases of hypertension of renal origin. Proof that this is the correct explanation of the arterial murmur is afforded by the complete disappearance of the murmurs when the artery is compressed by applying a second cuff below, thus shutting off the escape of the blood into the capillaries. By testing for the murmurs it is possible to keep daily supervision over the course of a primary or secondary affection of the circulatory apparatus, and guide treatment accordingly. In cases of aortic insufficiency of syphilitic aortic origin, no murmurs could be detected.

50 *Infantile Scorbutus; Twenty-Six Cases. J. Comby.
51 *Comparative Importance of the Luetin and Wassermann Reactions in Inherited Syphilis. G. Blechmann, M. Delort and A. Tulasne.
52 Icterus Gravis in Children. J. Comby.

50. **Scorbutus in Infants.**—None of the twenty-six infants with scorbutus whose histories Comby relates were breastfed or fed on fresh milk. After from five to ten months' feeding with commercially or home sterilized milk, the children began to grow pale and languid, and finally to cry whenever they were moved. The legs grew weak and as if paralyzed, a kind of pseudoparaplegia from pain. This is the most characteristic sign of incipient scorbutus. Hematomas may develop under the periosteum, but the most frequent symptom is the bleeding from the gums if the child has any teeth. Impress on the family the necessity to refrain from moving the child, especially from trying to make it stand up or walk; no bathing, merely leave the child quiet in bed, with plenty of air. Feed with fresh milk, boiled or not, and give a teaspoonful of orange or fruit juice between feedings. If no other fruit is available, lemon juice diluted and sweetened can be used. For children over a year old, three tablespoonfuls of soft mashed potato may be given during the day.

51. **The Luetin Versus the Wassermann Reaction in Inherited Syphilis.**—Blechmann and his co-workers have applied the luetin test to 230 children, and here report the details in 117 of the cases, including fifty with known or suspected syphilis. The Wassermann test was applied at the same time, and it harmonized much better with the clinical pictures than the luetin reactions, while the technic of the latter is more exacting. On the whole, they assert, a positive luetin reaction should be disregarded when the Wassermann and the clinical picture speak against syphilis. On the other hand, a positive Wassermann obtained on two occasions strongly suggests syphilis. In conclusion, they give tabulated findings with both tests in 274 cases of inherited syphilis as published by various investigators.

53 *Training Schools for Crippled Soldiers. (La rééducation professionnelle et la réadaptation au travail des estropiés et des mutilés de la guerre.) E. Mosny.
54 Frost-Bite. (Etude étiologique des froidures.) F. Debat.
55 *Specific Treatment and Prophylaxis of Leishmaniosis. (Bouton d'Orient.) Gachet.

53. **Training Schools for Maimed Soldiers.**—Mosny discusses what has been done in other lands for persons crippled by industrial or other accidents, and then describes the workings of the training school for crippled soldiers that has been at work at Lyons since last December. The men live in the school during their course of training, and the institution in various ways is a model. Another training school to teach horticulture is being organized. These, Mosny states, are the only practical realizations in France to date of aid by professional reeducation and readaptation to remunerative work for those mutilated or crippled in the war. At Lyons the men are taught to use the stump of the arm, without regard to an artificial limb. The prosthesis is to be selected later when the man has learned exactly what is best adapted to serve him in his work. Mosny discusses the general principles and special details of training the maimed to utilize the earning forces they have left, and of finding employment for them. It is a task the country must assume, he adds, and it will require all her ingenuity, all her material and moral forces, and all her goodness of heart. His plan contemplates loans to those who wish to set up a business for themselves.

55. **Oriental Sore.**—Gachet writes from the medical school at Teheran in Persia to extol the curative action of intravenous salvarsan treatment. The sore heals in from three to five weeks after one or two injections, with an interval of one or two weeks. He has found the Leishman bodies in the body of a fly common on dogs, the *Hippobosca canina*, and thinks that this fly has something to do with the transmission of the affection. Camels, horses and dogs are subject to it, but in Persia he has found it only in dogs; fifteen of twenty-one dogs brought in from the street showed the characteristic lesion. Intramuscular salvarsan injections cured them all in from three to five weeks. He adds that the fact that these lesions appear in man only on parts exposed, confirms the theory of fly intermediation in the transmission of the disease.

56 *Purulent Pleurisy as Complication of Artificial Pneumothorax. M. Jacot. Commenced in No. 3. Continued.
57 *Diuresis Induced by Intravenous Injection of Hypertonic Sugar Solutions. G. Turrettini.

56. **Purulent Pleurisy Complicating Induced Pneumothorax.**—Jacot discusses in this instalment the diagnosis, prognosis and treatment of this complication as observed in eight of 108 cases of pulmonary tuberculosis in which pneumothorax was artificially induced at Leysin. Purulent pleurisy is rare in ordinary pulmonary tuberculosis; Leudet found it only in nine of 2,000 consumptives. Some tuberculous focus perforating into the artificial pneumothorax is probably the cause explaining the purulent pleurisy. In treatment, even of the severest forms of purulent pleurisy, repeated puncture followed by insufflation of nitrogen is preferable to pleurotomy. It is free from the dangers of the latter while it maintains the therapeutic action of the induced pneumothorax, and adhesions rarely form with it while the chest wall is not left deformed as after a resection. Adhesions are particularly prone to develop after a lung has been compressed by the pneumothorax, and resection of the chest wall in treatment of the secondary purulent pleurisy is especially liable to bring this about, as it releases the lung from the compression.

57. **Diuresis from Sugar Infusion.**—Turrettini's experience has been unusually favorable with hypertonic sugar solutions in inducing diuresis in severe illness in which the kidneys had practically ceased to act. He gives the details of three cases of acute nephritis from poisoning with mercuric chlorid, two of uremia from nephritis plus atrophy of the kidneys, and one case of probable toxic action from some tuberculous focus elsewhere. The solution of glucose was of 25 or 40 per cent. strength, and the amount injected ranged from 300 to 500 c.c. each time. The condition was desperate in all the six cases, but these strong sugar solutions conquered the anuria in four cases and temporarily improved the kidney functioning in the fifth case before the patient died. Only one injection could be made in one case of severe mercurial poisoning as the vein could not be found.

59 *Treatment of Acute Pneumonia in Children. (Die Therapie der Pneumonie als therapeutisches Paradigma.) A. Baginsky.
60 *Stenosis of the Pylorus in Infants. M. K. Forcart.
61 Pathology of Periodical Vomiting with Acetonuria. H. Zade.

58. **Digestive Disturbances in Older Children.**—Baginsky discusses in turn habitual vomiting, nervous anorexia, atony of the stomach, chronic dyspepsia from gastric achylia, achylic diarrhea, and chronic constipation, and the general principles for treatment of each. Chronic constipation is sometimes managed best with a change of scene to supplement the change to an anticonstipation diet. No milk should be allowed until the child has learned to chew its milk instead of drinking it. He abhors purgatives and enemas in these cases except as the very last resort. Nervous anorexia is most common in children fed long on milk who have never learned to chew properly or are too indolent to chew. If they can be roused and trained to masticate they soon acquire an appetite. In some children the senses of taste and smell seem to be abnormally blunt so they thus lack the normal impulse to eat.

With chronic dyspeptic disturbances the main point in treatment is to determine what elements of the food the children are able to digest, and this requires study of the stools and tests of stomach functioning. Some digest fats; others are unable to tolerate them, and so on. Once the individual functional capacity is determined, the physician has the reins in his hands. Every relapse does the greatest harm, because the whole course of treatment has then to be begun over again. The less drugs are used, the better. A child with diarrhea must be kept unconditionally in bed.

59. **Treatment of Pneumonia in Children.**—Baginsky strives to impress on young physicians that the child has generally an intact organism, strong to resist and well equipped against pathologic damage, infections and intoxications. It reacts in the most gratifying way as a rule to slight therapeutic assistance. Strong drugs and methods are not required except extremely rarely, and then only in economical dosage. He reports the details of eight cases of pneumonia in children to serve as guides to therapeutic procedure in general. The main point is to trust Nature's recuperating powers, watching to reenforce her when she is not quite competent alone, always bearing in mind that, for children especially, we must refrain from doing harm by any unnecessary interference.

60. **Stenosis of the Pylorus in Infants.**—Forcart reports 15 cases; there was no nervous taint in the family. Nine of the children were the first born. Delivery had been normal in 11 cases. Only 4 of the children were breast-fed. The first symptoms of the stenosis developed in the second up to the seventh week of life. Thirteen were boy babies and all were much constipated. In only a third of the cases were there any signs of spastic phenomena elsewhere. Lavage of the stomach had no influence on the stenosis. One child died from inanition but 10 left the hospital entirely cured, mostly by the fourth to sixth week, but in some the stenosis kept up for from twelve to twenty weeks. If no benefit is apparent by the sixth week, an operation should be considered. The curves are given for each case, and the necropsy findings in the 3 that succumbed to pneumonia or inanition. No anesthetics or sedatives by the mouth gave any relief. The children's strength was kept up with nutrient enemas.

69 *Nature's Method of Autotrephining and Valve Production to Relieve Steeple Skull. (Ueber die Selbsttrepanation der Natur beim Turmschädel und über das Wesen des Turricephalus.) J. Strebel.
70 *Endemic Goiter. (Weitere epidemiologische Untersuchungen über den endemischen Kropf.) R. Klinger and T. Montigel.

69. **To Save Vision with Steeple Skull.**—Strebel discusses various typical shapes of the skull from premature ossification of the fontanels, especially as they affect vision and hearing. The last few years have brought a realization of the clinical importance of steeple skull, oxycephalus, turricephalus, hypsicephalus and pyrgocephalus, as they do not permit the normal expansion of the growing brain. The eyes protrude on account of the shallowness of the orbit with steeple skull, but the most serious consequence of it is the frequent atrophy of the optic nerve, with both central and peripheral loss of vision. Choked disk first develops, then optic neuritis follows, and atrophy is the next stage. It is a simple descending atrophy, from the mechanical injury of the nerve in the orbit or base of the skull or both, but the condition finally cannot be distinguished from true primary atrophy. In seven of nine such cases in the last four years, Strebel found evidences of this secondary atrophy. It develops usually before the age of 7, and boys are affected more frequently than girls. Headache and cramps have been noticed in some cases but as a rule there are no symptoms on the part of the brain. In two of Strebel's cases there were clonic convulsions with vomiting and loss of consciousness as signs of the chronic pressure on the brain.

In all cases of optic atrophy of dubious origin roentgenoscopy may first give the clue. It reveals further how Nature seeks to relieve in such cases by allowing holes to develop at the points where the skull is worn thin by the pressure. Holes up to 1 cm. long are worn through under the scalp and can be seen in the Roentgen picture. This is a kind of autotrephining, forming safety valves. Nature thus shows how to treat the disturbances from these abnormally shaped skulls. In one such skull there was one quite large hole and eleven small ones. As Strebel was examining this skull, it suddenly dawned on him that these holes explained why this person had had no visual disturbances during life notwithstanding the extreme steeple shape of the skull. Even the roofs of the orbits were worn through.

The roentgenograms in one case described in detail show the internal findings of pronounced steeple skull although externally it was scarcely apparent. In this family there was a history through four generations of congenital dislocation of the lens and congenital heart defects. Premature growing together of the fontanels is responsible for the trouble later; the brain continues to grow but there is not room enough for it in the prematurely solid skull. After blindness has once developed there is no chance for restoration of vision by any measures. But before this stage is reached, decompressive operations are liable to ward it off, making multiple openings where roentgenoscopy shows they are most needed. Family physicians and pediatrists should be on the lookout for a tendency to steeple skull; choked disk from this cause may develop in early childhood, even in the first months of life. The cases of partial turricephalus, without impairment of vision, demonstrate that Nature is able to cure or at least to arrest the tendency unaided. A visit to any blind asylum will usually show typical specimens of steeple skull, and Homer described a skull of this kind in Thersites. There are usually other anomalies in development in these cases, as Homer noticed.

70. **Endemic Goiter.**—Certain families and certain houses in the Swiss towns investigated show a remarkably large number of cases of goiter, but the water supply is the same as that for all their neighbors who are free from goiter. There is no direct inheritance of goiter, but there is unmistakably an inheritance of a predisposition to it when the exogenous factors come into play. Klinger and Montigel urge practitioners to collect family data on goiter.

78 Tabes Excludes Military Service. (Tabes und Heeresdienst.) G. Flatau.
79 Professional Secrecy from Medicolegal Standpoint. (Die Beschlagnahme von Krankengeschichten.) R. M. v. Olshausen.

71. **The War and the Nervous System.**—Redlich comments on the milder course of traumatic neuroses in this war in comparison with those in time of peace. The men affected are young and vigorous and the question of an indemnity does not influence the course, but the main factor, he thinks, in the comparatively favorable outcome is the authority of the discipline of military environment. The present experiences confirm Redlich's long held opinion that it is much better in cases of traumatic neuroses for the physician to refrain from paying too much attention to the patient's many disturbances, great and small. The physician's authority should be exerted to stimulate the patient to abstract himself from his troubles. In military circles, in the civilian population and in the refugees from the regions devasted by the war, the nervous system is bearing the strain far better than one would anticipate. Serious nervous affections seem to be restricted almost exclusively to those with a previous nervous taint. The predisposed break down, and melancholia and manic-depressive psychoses are comparatively common among such. Under ordinary circumstances their predisposition might never have been roused from its latent phase. In conclusion Redlich remarks "In future not only medical men and theorists but economists and statesmen will have to pay more attention to eugenics and to the training of the young in character and in physical endurance as well as training the mind. The longing for an everlasting peace will still be a Utopian dream in times to come as in the past. Hence we must do everything to promote efficiency and resisting power in young and old."

72. **Treatment of Concussion of the Brain.**—Weber refers only to cases in which the man was totally unconscious for a time after the injury, usually a fall on the head, or a wound of the skull from a bullet or scrap of shell, without actual lesions of the brain. The disturbances that follow are generally headache, restless sleep, dizziness in climbing stairs or walking fast, and inability to do any muscular work, sweating and having to give up when such is attempted. He has found that in such persons the distribution of the blood during muscular exertion differs from the distribution under normal conditions. The concussion injures the central mechanism for the innervation of the blood vessels; both the peripheral and the cerebral blood vessels are involved. It seems plausible to assume that this is the cause of the headache and other symptoms which follow and persist after concussion of the brain. The headache and dizziness are connected with the damaged central mechanism for the innervation of the vessels, as also the weakness and inability to do muscular work. In treatment, drugs gave no relief but surprising benefit was realized from alternating hot and cold douches. At first the relief is transient, but the improvement becomes permanent under a course of the alternating douches. The relief is striking within half an hour even after one alternating douche and in two or three weeks the improvement becomes a complete cure. The douches are given with hot and cold water for half a minute each (14 and 45 C. or 59 and 113 F.) applying the cold jet a trifle longer than the hot, and ending always with the cold. The cold seems to be the active factor; its effect is merely enhanced by the hot jet. Seven cases are described to illustrate the prompt and reliable curative action of the procedure in these conditions, and Weber also describes how he registers the dilatation of the vessels in the hand or forearm during some strictly localized muscular exertion, such as dorsal and plantar flexion of the foot, hanging free. After concussion of the brain the vessels shrink, instead of becoming distended, during this muscular exertion.

73. **Hygiene in the Field.**—Among the various measures enforced or contemplated to keep the troops in health, Kuhn and Möllers mention that it is the plan to repeat the antityphoid inoculation after a five-month interval. Every tuberculosis suspect is sent home, and careful search is made through the civilian population for consumptives and suspects, and they are isolated in the public hospitals if possible. When this cannot be done, they are left in their homes; the houses are placarded and all intercourse with soldiers is prohibited.

76. **Nonalcoholic Drinks.**—Fehsenfeld has made a special study of the various beverages on the market which contain no alcohol. He has thus tested the output of fourteen firms; their fruit juice and malt beverages are kept from spoiling by pasteurizing, by thickening with sugar or by vacuum distillation. They are nutritious while supplying the mineral salts, etc., urgently needed by the tissues. From every point of view they are desirable except that one tires of them more easily, and that they do not have the same appetizing effect as alcoholic beverages. They are also more liable to adulteration and to the use of harmful preservatives. But since the Freie Vereinigung deutscher Nahrungsmittelchemiker, an association of food chemists, set up standards for such beverages in 1911, a large number of very good alcohol-free wines, beer and sterilized fruit juices have been put on the market. The main thing now is to uproot the tradition that a jolly company must have alcoholic drinks to be a success, and further, to convince the public that the amounts of alcohol which are extremely moderate for one person may be far too much for his neighbor. It must also be impressed on the public that even the "extremely moderate" use of alcohol is not always free from danger.

77. **Walking Casts.**—Köhler and Gerson give illustrated descriptions of inexpensive plaster splints and casts, with strip-iron stirrups, which allow the patients to be up and about. Gerson's cast not only immobilizes but exerts adjustable extension. This is realized when the patient is sitting or standing by overalls fastened to the stirrup and held up by suspenders. The pressure from the overalls on the stirrup and thus on the cast is ample to hold the cast in place and thus keep up the extension for a fractured femur, for instance. The pelvis and hip are not included in the cast; it fits against the tuberosity of the ischium. The cast can be cautiously pulled off at any time for inspection and massage of the limb, and the foot can be massaged and exercised without disturbing the apparatus.

83. **Operative Treatment of Elephantiasis.**—Two years have now elapsed since Kondoleon first excised the deep fascia in the leg to improve conditions in chronic edema with elephantiasis. Several have applied this technic since, including Royster, whose favorable report was published in The Journal, May 30, 1914, p. 1720. Kondoleon has performed the operation on eleven patients, in four cases on both legs. The details and the ultimate outcome in ten cases are given in full. Two of the patients were entirely cured and three materially and permanently improved; two were slightly *improved and in one patient the former condition returned.* The outcome is not known in the other cases. Improvement occurred constantly when the tissues were still comparatively elastic; the failures were only in the very old, chronic cases with tough, hardened soft parts. The complete cures and the essential improvement realized in a considerable proportion of the cases are particularly gratifying, as we previously have had no means to influence this affection. Kondoleon does not describe his technic here, but it was given in The Journal, Sept. 12, 1912, p. 977, from his early report on the subject.

86. **Air Treatment of Gunshot Wounds of the Lung.**—*Ehret says that none died of the 100 soldiers with gunshot* wounds of the lungs he has examined or treated from five to twenty days after their injury. He ascribes this favorable outcome to his practice of puncturing the chest cavity and letting in air. This aids in expelling all secretions, and the pressure of the air tends to prevent bleeding and reduces the tendency to retraction and adhesions which are so common with gunshot wounds of the lungs not treated in this way. Even when the exudation is not enough to require puncture, yet adhesions are warded off better by this puncturing and letting in air. It is possible but not yet definitely settled that *the artificial pneumothorax thus induced may break up adhesions* already formed of recent date. He uses ordinary air and has never had any unpleasant by-effects with the method.

87. **Bayonet Wounds of the Lung.**—Herrenschneider reports a case in which a bayonet had passed through the entire chest, entering the right fourth interspace and emerging near the third thoracic vertebra. After the first day or so the temperature was normal or nearly so and except for a slight cough without expectoration the man suffered no discomfort. The pleural effusion was sterile at first but later an anaerobic bacterium was cultivated from it. Treatment was with absolute repose alone, except that a little codein was given to suppress the slight cough, and in less than six weeks after the injury the man was able to leave for home to complete his convalescence. Such experiences testify that it is not necessary to resect ribs, as some advise in treatment of bayonet wounds of the chest.

88. **Ligation of the Common Carotid.**—Various measures have been proposed to ward off the serious results liable to follow the sudden shutting off of the supply of blood to the brain by ligating the common carotid. Smoler advises slow "strangling" of the artery, shutting off the circulation by stages as it were, and Ceci advises ligating the internal jugular vein at the same time as the artery, thus impeding the escape of the blood from the brain. Riedinger recently had a soldier in his charge who had been shot just below the right mastoid process, the bullet passing out through the floor of the mouth. Serious arterial hemorrhage came on the eighth day and recurred again and again. Riedinger threw two ligatures *around the common carotid and also around the* internal jugular vein. No disturbances on the part of the brain were observed and the wound healed promptly. This experience sustains Ceci's views as to the advisability of ligating the vein at the same time as the artery.

91. **Nervous Affections from Wounds in War.**—Saenger reports a number of interesting cases encountered at Hamburg among soldiers wounded in the head or spinal cord, and discusses a number of special points. This war has shown that concussion or commotion of the spinal cord is liable to arrest temporarily its functioning even when the cord itself was not touched by the bullet. There does not seem to be any special "war neurosis," but pathologic psychic reactions to the stress, both physical and emotional, of the war are common in the predisposed. He deplores Oppenheim's recent revival of the idea of "traumatic neuroses," saying that this conception should be repudiated not only from the scientific but from the practical standpoint on account of the enormous economic burdens it would impose on the state if generally accepted. In conclusion he relates five cases among the civilian population of Hamburg in which emotions connected with the war have led to acute mania or suicide. Numbers of other cases have also occurred, but, on the other hand, he remarks, many persons with unstable mind or nervous system have been steadied and helped by the war. In conclusion he quotes Hindenburg's prophecy: "The victors in this war will be those with the stoutest nerves."

98 Sterilization of Clothing with Fumes of Carbon Disulphid. (Neues Entlausungsverfahren.) E. Eckert and A. Fuchs.

96. **Involvement of the Kidneys in Relapsing Fever.**—Jarno remarks that in the accessible literature he has found mention of merely traces of albumin in the urine or hemorrhagic nephritis as the only renal complications of relapsing fever. In his extensive experience at the contagious disease hospital at Ruma, he has found albumin constantly, sometimes in large amounts, and frequently accompanied by granular tube-casts. The findings in 170 cases are tabulated; the albumin appeared in the urine the very first day as a rule and by the second day there was up to 0.5 and 1.5 per thousand and masses of tube-casts. The findings in the urine keep up during the attack but disappear after defervescence, the urine being quite normal by the fourth day. These phenomena recur regularly with each of the relapsing attacks, and the normal urine afterward demonstrates that apparently no serious damage has been done the kidneys. In only one of all his cases have the albuminuria and casts persisted indefinitely since. Hemorrhagic nephritis as a complication was encountered only twice and there was no macroscopic blood. The clinical picture of relapsing fever, including the kidney findings, was favorably influenced by neosalvarsan and to a remarkable extent. As the spirilla are killed off by this drug, the kidneys escape further injury.

97. **Improved Technic for Determination of Typhoid Bacilli in Stools.**—Jaffé expatiates on the superior advantages, the ease, and the reliability of Bierast's benzin method of treating the stools of suspected typhoid carriers. The benzin seems to destroy some substance in the membrane capsule of colon bacilli, and they die off in consequence, while the typhoid and paratyphoid bacilli are not injured by it enough to check their growth. The delay of sixteen hours before the test is conclusive, he says, is a slight drawback which is outweighed by the advantages of the method. The findings in fourteen cases are tabulated. In four cases typhoid bacilli were demonstrated by this means when other methods gave negative results. In the five other positive cases, the typhoid bacilli were in pure culture or there were merely very few colon bacilli in comparison with the luxuriant growth of the former on the ordinary plates. One of the advantages of the technic is that the entire specimen of stool is treated. It is rubbed up with bouillon to a thin suspension. The benzin is then poured on it, as thick as one's thumb, and the glass vessel is corked and vigorously shaken up. Unless the cork is sound and tight, some of the vessel contents might get on the fingers. Bierast himself contracted typhoid, probably in this way, while studying out this technic, and a bacteriologist in a hospital near Vienna has succumbed recently to

typhoid acquired in this way. A rubber cap might be used to cover the top of the bottle, or the benzin might be merely stirred into the suspension. The aim is to expose the colon bacilli to the benzin as thoroughly as possible. The vessel is then set away in a cool place, protected against the light, for sixteen hours. Then one or two drops from the lowest brownish strata are transferred to a series of Drigalski or Endo plates.

April, No. 4, pp. 121-160

100 *Chronic Painful Nephritis with Apparently Normal Urine; Two Cases. W. Misch.

99. **Comparison of Tests of Kidney Functioning.**—In this communication from the medical clinic at Vienna in charge of Ortner, the detailed findings in the urine with various tests are tabulated, under ten headings, from sixty-eight patients with internal disease, mostly of the kidneys. The elements that make up the Ambard formula are also compared, and the correspondence between the Ambard findings and the clinical picture and course is emphasized. The essential feature and the progress realized with the Ambard method are that no attempt is made to record and compare the intake or elimination of nitrogen. It aims merely to estimate the proportion of urea and of chlorids in the urine and blood at a given moment, and compare the figures. Contradictory findings were never encountered in any of the sixty-eight cases studied; the clinical course and the Ambard findings always harmonized. The figures in the index were within normal range in every case in which the kidneys were sound. For convenience, Bauer classifies nephritis in three groups: glomerular nephritis in a first, second or third stage; nephrosis, alone or associated with glomerular nephritis; and sclerosis, bland or combined with nephritis. The Ambard findings in each group are compared and discussed and the comparatively simple and rapid technic is extolled as well repaying study. (The Ambard formula was described in The Journal, March 7, 1914, p. 813. His "uremic constant" is the constant ratio between the urea in the blood and the square root of the urea in the urine.)

100. **Chronic Painful Nephritis with Apparently Normal Urine.**—The patients were men of 28 and 45. The attacks of pain in the left kidney region in the first case were so severe that decapsulation was done, which put an end completely to the pains. A scrap cut from the kidney showed evidences of chronic parenchymatous nephritis and yet no albumin nor tube-cast had been discovered in the urine. There was a history in this case of an inflammatory affection of this kidney a few months before, but in the second case no pathologic antecedents were known. This patient also was relieved of all pains by decapsulation of the painful kidney. Misch queries whether this painful nephritis without urine findings may not be merely an early stage of nephrolithiasis. Decapsulation seems to answer the purpose completely. A permanent cure was realized by it in these cases and also in a number in the literature to which Misch refers.

Gazzetta degli Ospedali e delle Cliniche, Milan

April 18, XXXVI, No. 31, pp. 481-496

101 *Croup and Tracheotomy. F. Marinelli.

101. **Tracheotomy in Croup.**—Marinelli presents an array of arguments to impress on the general practitioner the value of tracheotomy for stenosis in croup, and the necessity for his familiarizing himself with the technic so that he can apply it in time. He reports twenty-seven cases to demonstrate the advantages of tracheotomy, making the incision with a bistoury, below the "isthmus" of the thyroid, and only barely large enough to admit the cannula. The patient's breathing must be supervised day and night, and the cannula be discarded at the earliest possible moment. He declares that in general practice tracheotomy should be preferred to intubation, for one reason, because it is the best means at our disposal to ward off secondary pneumonia. He advises it in every case in which the usual measures are not followed by evident improvement. General anesthesia is contraindicated as liable to aggravate the postoperative condition.

104 *Pseudotetanus from Diplococcus Sepsis. T. Pontano.
105 Pathogenesis and Prognosis of Pulsus Alternans. G. Galli.

102. **Iodin in Erysipelas.**—Magi relates that in his experience painting the inflamed region abundantly with tincture of iodin had an "actually brillant effect" on the infectious process, especially with enlargement of the lymph glands in the arm following infected wounds of the hands. The lymphangitis subsided almost constantly after once painting with the iodin, and rebellious erysipelas yielded to repeated applications. In the severest cases he supplemented this with antistreptococcus serotherapy. An attack of erysipelas of the face and scalp on the assistant surgeon at the clinic also yielded promptly to the iodin treatment.

104. **Diplococcus Pseudotetanus.**—Pontano's patient was a man of 77 with an acute toxi-infectious general condition plus a neuromuscular syndrome with painful contracture and intentional spasm. The two syndromes had developed simultaneously, everything suggesting a symptomatic tetaniform status from the same cause responsible for the acute fever and general depression. No benefit was derived from quinin or vigorous salicylic medication. A diplococcus was cultivated from the blood, but the cerebrospinal fluid gave negative findings on repeated examination. Transient benefit was derived from a silver salt injected intravenously, but the condition grew progressively worse, with death the twenty-ninth day after entering the hospital. He had had diffuse pains in the limbs and joints for a few days before the fever developed, and one year before had had an attack of pneumonia, but otherwise no pathologic antecedents were known.

106 *Primary Alcoholic Degeneration of Corpus Callosum. (Morbo di Marchiafava.) P. Guizzetti and G. Tomasinelli.
107 *Cultivation of Tetanus Bacilli from the Blood. G. Sinigaglia.

106. **Primary Alcoholic Degeneration of the Corpus Callosum.**—Guizzetti relates that Marchiafava was the first to call attention to this primary degeneration of the nerve fibers in the corpus callosum and commissure in men with alcoholic psychoses. The clinical picture in this condition is that of a gradually developing feeblemindedness, with perversion or deadening of the moral sense; there may also be tremor and disturbances in speech, etc. Guizzetti reports, with illustrations of the necropsy findings, a case in a man of 55 who had died of pneumonia. The middle stratum of the corpus callosum and middle of the anterior white commissure showed systematized primary degeneration, but not so extensive as in most of the other cases recorded. For the last few years there had been a gradually increasing tendency to loss of memory, failure at times to comprehend what was said to him, inability to attend to matters outside of his regular routine as meter inspector, and for some years he had complained of headaches and occasional dizziness. He was not a very hard drinker, and his mental impairment had not been severe enough to cost him his position. Guizzetti has since reviewed the 13,000 necropsy reports at the institute of pathologic anatomy in his charge but was unable to find any record of a similar primary degeneration of this region, although he found three cases of ischemic softening, one of primary tumor and one of a metastatic tumor at this point.

107. **Tetanus Bacilli in the Blood.**—Sinigaglia discusses what has been published on this subject and compares with it a case from his own practice in which he was able to cultivate tetanus bacilli from the blood. His patient was a boy of 10 who had stepped on a nail, October 11, signs of

tetanus developing on November 9. Cultures were made from the blood November 16, and two microbes developed, one evidently the tetanus bacillus, and causing tetanus in animals inoculated with it. The tetanus bacilli were not numerous in the blood and seemed to sojourn there only temporarily, but still the blood might serve as a vehicle for infection in case of an operation on a patient with tetanus.

109 *Vagotony. J. de Monlevade.

109. **Vagotony.**—Monlevade has been studying in Austregesilo's service the effect of atropin, pilocarpin and epinephrin on the sympathetic and vagus nervous systems, comparing his findings with those that have been reported by other authors as types of pure vagotony and of what he calls "status vagotonicus." The latter is found in connection with various clinical pictures, on which it imprints a special stamp. Neurasthenia, for instance, epilepsy, or hysteria may be accompanied by a confused and vast train of symptoms on the part of the heart, the digestive tract, the respiration or the vasomotor system, all of which are merely the manifestations of this excessive excitability of the vagus nervous system. Among the infectious diseases, tuberculosis stands at the head with vagotonic disturbances from its very inception. Upsets in the ductless gland system are also fields in which vagotony flourishes exceptionally luxuriantly, as in Addison's disease and exophthalmic goiter. Gastric ulcer may develop in some cases with vomiting, hyperchlorhydria and constipation while other cases are free from them. In the first group the status vagotonicus modifies the clinical picture. Six typical cases of this kind are related, with the response to epinephrin and pilocarpin tests. In every case the reaction to epinephrin and to pilocarpin was exactly the reverse; when one was positive the other was negative.

114 Study of the Normal Carotid Pulse. (Bijdrage tot de kennis van de polskromme. I.) L. Kaiser.

112. **Tuberculosis in the Tropics.**—Van Loghem is chief of the department of tropical hygiene in the Colonial Institute of the Netherlands, and he has been making a special study of tuberculosis in the Dutch East Indies. He compares the general and the tuberculosis mortality, 1900 to 1904, in thirty-two large cities of the world. Amsterdam and Christiania head the first list in Europe with a general mortality of 15.3 per thousand inhabitants. In Asia, Tokyo heads the list with 18.3 per thousand. Calcutta had 39.3; Manila, 46.7; Batavia, 53.2, and Bombay, 71.4 per thousand. The tuberculosis mortality parallels this range to some extent, Amsterdam having 1.52 per thousand; Tunis, 6.91; Bombay, 6.35, and Batavia, 4.09. New York is cited at 2.21 per thousand.

Van Loghem remarks that as we are learning to keep yellow fever and other tropical diseases under control, tuberculosis in the tropical regions is coming in for greater attention. Study of tuberculosis under tropical conditions is liable to throw light on many of its problems elsewhere. As an example of this he points out that bovine tuberculosis in recent years seems to be spreading, and the milk from tuber ous cows is being used by children and adults more than er before, and yet human tuberculosis shows a downward dency everywhere. He regards this as evidence of the identity of bovine and human tuberculosis. The experiences in the tropics sustain this view. For instance, he relates that the stock of cows in the Dutch East Indies is free from tuberculosis. By strict supervision infection from importation of bovine tuberculosis has been warded off, and yet the figures cited show that human tuberculosis is very prevalent. It must have developed without any basis of bovine tuberculosis, as there is none in the islands. These facts settle also the question as to the possible mutation of human into bovine tubercle bacilli, which some have deemed possible. It certainly has not occurred to date in Netherlands India, he affirms. Although human tuberculosis is common, yet the cattle have kept free from it.

Conditions in the tropics throw light further on the influence of infection in childhood on tuberculosis in later life. In the remote interior of the islands, the Pirquet skin tuberculin test has shown that large areas of country are entirely free from tuberculosis. The more intercourse there is with Europeans and Americans on the coast and in the cities, the greater the spreading of tuberculosis to invade the virgin areas from the large centers. In the persons thus attacked for the first time the disease does not behave as in Europeans and Americans who have been immunized to a greater or less extent by infection in childhood. It runs an acute course in young and old alike, very much like the course of tuberculosis in children in the western world. He suggests that it might be well to vaccinate against tuberculosis in these virgin regions, aiming to realize an effect like that realized in Europe and America by the systematic natural vaccination which repeated opportunities for infection confer on the young as they grow up. He remarks that under modern hygiene and control of open tuberculosis, the number of tubercle bacilli in the external world is certainly growing less and less. This suggests that a time is coming when the young will not have the repeated opportunities of the present and past for infection. The young will grow up free from tuberculosis, but, when opportunity for infection does arise, they will be practically virgin soil, like the natives in the interior of tropical islands, and the disease when it attacks them will run the acute course of the nonimmunized. It is possible that Europe may have to face a new invasion of tuberculosis with an acute course and high mortality unless it can be stamped out by vaccination, as smallpox has been rendered harmless in parts of Europe, or unless it can be eradicated like leprosy.

THE RATIONAL TREATMENT OF HODGKIN'S DISEASE *

J. L. YATES, M.D.
MILWAUKEE, WIS.
AND
C. H. BUNTING, M.D.
MADISON, WIS.

INTRODUCTORY

A combined pathologic, experimental and clinical study of Hodgkin's disease extending over a period of six years is the basis of this communication. The most efficacious methods of treatment will be presented with sufficient data to justify the various therapeutic procedures held to be indicated. Fischer[1] was unable in 1901 to find a record of a single case in which cure was *permanent*. None has since then been reported in the literature up to the present year. We have been so fortunate as to have seen two recoveries (that is, five years without evidence of the disease) and at present have a small number of patients under observation who are in a very encouraging condition three to six years after beginning treatment. We believe the disease more common than supposed, more protean in its clinical manifestations than is generally accepted, and not of necessity universally fatal.

This is to be regarded as a statement of observations made and an indication of the results attained by the practical application of the lessons drawn from those observations, laboratory and clinical. Although it is not claimed that a satisfactory routine method of treatment has been established, we feel that a single recovery is indeed encouraging and that prolongation of life, reduction of discomfort and the distinct possibility of 10 per cent. of ultimate cures justifies a conviction that our therapeutic principles are to some extent well founded.

DEFINITION

Hodgkin's disease may be tentatively defined as a non-contagious, infectious granulomatous process due to the *Bacillus hodgkini*. Primarily localized at or about a portal of entry, it causes a progressive enlargement of a specific nature in adjacent and remote preexisting lymphoid structures, and early provokes characteristic changes in the blood picture. Once well established, the disease manifests little or no tendency to spontaneous recovery.

ETIOLOGY

A pleomorphic diphtheroid organism, gram-positive, antiformin-fast but not acid-fast, has been grown almost constantly,[2] and usually in pure culture from fresh tissue showing the characteristic pathologic changes in the disease. It has been stained in situ in affected tissue where it may occur in large numbers in an acute process and apparently be the only microorganism present. Subcutaneous inoculation in pure culture into monkeys has provoked a series of changes quite analogous to the disease as manifested in its more acute form in the human. Recovered in pure culture from lesions in a monkey in which the disease had become established, the inoculation of another monkey therewith induced a similar affection as did likewise a subcutaneous transplant of an involved gland from an affected to a normal monkey.[3] Moreover, the monkeys soon after inoculation show changes in their blood pictures identical with those observed in spontaneous human cases. Similarly the subcutaneous injection into a quite normal individual of five, ten and twenty million bacilli of a polyvalent stock Hodgkin's vaccine at intervals of five days has produced within four days of the last injection the blood changes which Dr. Bunting[4] has shown to be an almost constant characteristic of the disease.[5]

Diphtheroid organisms are widely distributed[6] and are being cultivated from a variety of pathologic tissues. Until the identity of the *B. hodgkini* has been determined accurately it will be impossible to fulfil Koch's dicta to the letter, yet from the facts already established it would seem justifiable to assume that the causal relationship of this organism to the disease has been demonstrated.[6]

[5] Solely for the benefit of the antivivisectionists be it known that the above mentioned individual was a physician who understood the nature of the experiment.

[6] It has been so long and so widely held that Hodgkin's disease was of an infectious origin that attempts have been made by many investigators to isolate organisms from tissue obtained at operations or post mortem. Cocci were found first (Verdelli: Centralbl. f. Med. Wissensch., 1893, xxxi, 545); later various cocci and bacilli (Brigidi and Peccoli: Ziegler's Beitr., 1894, xvi, 338) leading to a suspicion that a number of bacteria might be causative agents. Delbet isolated a bacillus (Delbet: Compt. rend. Acad. d. sc., 1895, cxx, 1373) which was not described, and was said to have caused characteristic glandular enlargements after intraperitoneal and subcutaneous injections into dogs. Emulsions of glands have been injected into various animals, and if there was not a concomitant tuberculosis the results were quite negative. Thus Longcope produced transient glandular enlargements in monkeys (Longcope: Bull. Univ. of Pennsylvania Med. Dept., 1907-8, xx, 229) which failed to show characteristic pathologic changes. A possible relationship to syphilis has repeatedly been suggested. Spirochetes were said to have been stained in sections of typical glands (White: The Journal A. M. A., Aug. 31, 1907, p. 774) but this has lacked confirmation through a positive Wassermann reaction (Caan: München. med. Wchnschr., 1910, lvii, 1002) has been obtained in cases giving a negative luetic history. As a heritage of the belief that Hodgkin's disease was an atypical tuberculosis, Fraenkel and Much have held that an organism which they obtained with great regularity from various affected tissues by an antiformin method was a granular, nonacid-fast tubercle bacillus. (Fraenkel and Much: Ztschr. f. Hyg. u. Infectionskrankh., 1910, lxvii, 159.) They were unable to obtain a culture of this organism or to reproduce the disease by inoculation of animals with the filtrate which contained it. It is probable that they were dealing with *B. hodgkini*.

Nothing is known of the occurrence of *B. hodgkini* outside the human body. Clinical evidence indicates that it may enter through other portals than those situated in the gastro-intestinal tract. It is at least suggestive in this connection that so-called pseudoleukemia has been described as having occurred in swine;[7] in a horse;[8] in chickens;[9] in dogs,[10] and in sheep.[11] In the last animal the disease is claimed to be infectious and to be transmitted by insects.

GENERAL PATHOLOGY

Since the publication of Dorothy Reed's paper[12] twelve years ago, subsequent pathologic descriptions of the more common types of the lesions have been largely repetitions of her observations. With the realization that Hodgkin's disease is probably less limited in its clinical manifestations than was held at that time, and in the light of present conceptions, other less generally accepted lesions should be included in the category. These variations, however, are quantitative rather than qualitative and no radical additions can be made to Dr. Reed's splendid fundamental contribution to this subject.

For example, we have observed two adults showing clinical and pathologic characteristics of a type of lymphosarcoma who had a positive Hodgkin's blood picture, and from whose excised glands an organism identical with or closely related to the *B. hodgkini* was cultivated. In both the disease was first noticed in an enlargement of inguinal glands. Histologically these glands showed an almost complete obliteration of the normal architecture and a widespread proliferation of the "endotheloid" cells particularly marked in numerous foci which on fresh gross section gave an appearance suggesting miliary tubercles.

A man, aged 64, suffering from chloroma in its most typical advanced form, clinical and pathologic, presented a characteristic blood picture, and mediums on which were implanted pieces of excised glands gave pure cultures of what appeared to be the Hodgkin's organism. Macroscopically the greenish tint was evident in a fresh section; microscopically a proliferation of atypical large lymphoid cells and the presence of occasional "giant" endothelioid cells and numerous accumulations of blood pigment were particularly noticeable.

Still more surprising were the results of observations on a young physician who had for seven years been suffering from periodic attacks of a peculiar type of subcutaneous inflammation associated with pain, fever, delirium, leukocytosis, lymphangitis and lymphadenitis affecting one leg and causing a very gradual enlargement suggesting elephantiasis. His blood picture was that of Hodgkin's disease both between and during attacks. Cultures taken from obviously involved subcutaneous fat and from enlarged popliteal glands developed an apparently characteristic diphtheroid organism. Sections from the fat showed a definite perivascular inflammation, a mononuclear cellular infiltration and fixed tissue proliferation. Those from the glands showed a distortion of architecture, proliferation of endothelioid and lymphoid cells with scattered endothelioid giant cells and with a fine, diffuse, fibroblastic proliferation. A periadenitis of character similar to the perivascular inflammation in the fat was also present. Eosinophilic infiltration was lacking.

The successful cultivations of a similar organism from the spleen pulp after splenectomy in two cases in which a clinical diagnosis of early Banti's disease had been made are very suggestive, particularly since it has been held (Westphal) that there is a purely splenic type of the disease. In these instances the blood picture was not quite positive because of the absence of an increase in the size and number of the platelets. Microscopically there was the usual increase in stroma, destruction of the malpighian corpuscles and excess of the endothelioid cells. The cultivation of a characteristic organism from the glands in a case of lymphatic leukemia by Steele and the observations of the Fraenkel-Much granular bacillus in this disease are suggestive, but only suggestive, of a possible relationship of these diseases and not proof of their identity.

A middle-aged woman with moderately advanced arthritis deformans had, in addition to carious teeth wonderfully masked by most artistic crown work, obviously affected tonsils and enlarged inguinal glands. Cultures made from these glands developed a diphtheroid bacterium in pure culture, a section therefrom showed histologic changes indicative of Hodgkin's disease and virtually conclusive additional evidence was in the changes in her blood picture. As a corroboration of these findings may be cited the observation of another patient suffering from Hodgkin's disease in a subacute form who has had, but only since the affection became well established, recurrent attacks of multiple arthritis apparently attributable to no other infection.

Certain erroneous statements are frequently encountered, quotations from observations made when pathologic and clinical diagnoses differed from present standards. Some have a definite therapeutic significance and should be refuted.

It is incorrectly maintained that the capsules of lymph glands are never penetrated and that the periglandular tissues are therefore not directly invaded by the intraglandular granulomatous process. This capsular penetration is unusual and is only marked when the disease is progressing acutely. It has also been held that there is no periadenitis, hence no matting together of the glands or formation of adhesions to the skin or deeper structures. This too is incorrect. A periadenitis is virtually constant, probably developing from a [illegible] dissemination occurs, indeed virulent [illegible] are to be found in the periglandular tissues. These periglandular tissues, as pointed out by Fischer, are moist, vascular and friable in acute or recent involvements and are more apt to be dry, avascular and firm in the older and more chronic varieties. Thus, without evidence of secondary infection, intimate and dense adhesions to the skin occur and rarely may even lead to ulceration, according to Delbet.[13] The brawny induration of the skin present in several of our cases indicated that certain of the board-like subcutaneous inflammations might be due to the *B. hodgkini*, and this has been already confirmed in a case cited above.

Likewise more or less conspicuous and dense adhesions are found between the glands themselves and surrounding deep structures, often leading to an erroneous conclusion that a malignant type of infiltration has been encountered. The fluctuations in the size, consistency and degree of mobility so often noticed in the course of the disease are probably attributable to a large extent to waves of intensity in this periadentitis.

Contrary to a frequently repeated statement, foci of macroscopic softening do occur, without any secondary infection, though but rarely, and then particularly in the more acutely affected glands. When the process is older or more chronic there is a correspondingly increasing sclerosis which virtually becomes complete if life is sufficiently prolonged. Even when there is little to be found microscopically except fibrous tissue the organism can be cultivated with proper technic.

LIVING PATHOLOGY

Since the living pathology of any disease is a foundation for its therapy an attempt will be made to portray that of Hodgkin's disease as we have come to see it through superimposed pathologic and clinical spectacles.

When Wilks gave to Hodgkin's disease an intermediate position between cancer and tuberculosis he did all three an injustice. Hodgkin's disease may be said to possess all of the evil clinical characteristics and none of the virtues of both a malignant neoplasm and a malign infection. By the latter is meant an infectious process in which the balance of power between virulence and resistance is so delicately adjusted that it may be disturbed by factors frequently unrecognizable and usually negligible under other conditions. In the constant struggle for supremacy the powers of resistance ultimately succumb, but only after repeatedly having overcome the temporary advantages gained by relatively or actually increased virulence.

The offensive mechanism may be regarded as both neoplastic and inflammatory *in its effects*, attributing to the former, more particularly, the mechanical or physical injuries and to the latter more especially the toxic or physiologic.

With the establishment of a portal of entry, a lymphangitis partly toxic and in part due to the presence of bacteria marks the first extension of the disease toward the next lymphadenoid station, there to provoke a specific lymphadenitis. Perilymphangitis and perilymphadenitis are significant and constant features in the process. The entire progress of the disease is a repetition of similar steps, now more acute, now less, increasing numerically here by arithmetical there by geometrical progression, almost never constantly but in alternating waves of progression and regression due probably to periods of disproportion between the powers of virulence and resistance, and varying directly with the degree and duration of this inequality, being at times well localized, at others quite general.

Thus may be explained at the one extreme the extension between glands or groups of glands without any notable concomitant reaction, and at the other extreme those characteristic recurrent febrile attacks.

Three stages of the disease may thus roughly be outlined:

Stage 1. Process localized, physical effects slight, physiologic effects usually unnoticed, though a positive blood picture, an expression of toxemia, is already developed.

Stage 2. Considerable dissemination, physical effects more marked but still relatively insignificant, physiologic effects now definite, toxemia and anemia.

Stage 3. Wide dissemination, physical effects pronounced, edema, dysphagia, dyspnea, physiologic effects advanced, toxemia, anemia and cachexia.

Manifestly, in any given case, the variations in extent and intensity of the physical and physiologic effects present diverse problems in diagnosis, therapeusis and prognosis.

Apparently local and general resistance may be estimated to some extent histologically. The end-result so far as local recovery is concerned is fibrous tissue. An index of the general resistance can be found in the blood picture where there seems to be some direct significant relationship between a normal proportion of small lymphocytes and a favorable prognosis.

Sarcomatous metamorphosis in Hodgkin's disease has been described by Yamasaki,[14] Karsner[15] and Symmers.[16] A necropsy in the most acute and extensive case we have seen showed the parietal pleura, visceral pericardium, intercostal and pectoral muscles to be riddled with nodules. Macroscopically the appearance of malignancy was as distinct as was the picture of typical Hodgkin's granulomatous infiltration, microscopically. The possibility of malignant metamorphosis must be admitted, also its improbability, inasmuch as the causative agent is to be found in and to be cultivated from these so-called malignant metastatic lesions.

Confusing complications of secondary infections, other than agonal, occur and may make a certain diagnosis extremely difficult. When tuberculosis is engrafted on an established Hodgkin's process, as not infrequently occurs late in the disease, the histologic diagnosis is simple. Exceptional cases are reported, as cited by Fischer and Dietrich,[17] in which the two diseases were thought to have developed simultaneously. These should present little difficulty of recognition from a pathologic point of view at least. If any such cases have come under our observation they have been unrecognized. The greatest difficulty has been encountered when, apparently, Hodgkin's disease may have been engrafted on an old tuberculous adenitis in which there exists both caseation and secondary acute infection. We have two such cases under treatment. Glands obtained at two operations on bilateral cervical enlargements of one individual showed advanced tuberculosis with much caseation and some less chronic changes that could not with certainty be identified. Cultures give cocci. *B. subtilis* and in one tube a diphtheroid bacillus which could not be isolated. Definite evidence of an acute infection grafted on a Hodgkin's disease has not yet been established in our work.

CLINICAL HISTORY

Heredity and contagion are without apparent significance, though a case cited by Albutt is still quoted as indicative of the latter being a possibility. Unhygienic surroundings may have some influence, particularly deficient personal cleanliness. No age is exempt, and contrary to the usual statement the sexes are about equally affected, though in males the disease is apt to develop in younger individuals.

Almost every conceivable condition supposed to reduce resistance has been suggested repeatedly as a predisposing factor. It is an interesting coincidence that diphtheria has been mentioned but once in the literature to which we have access.[18] Robust young persons are attacked while in apparently excellent health; more often perhaps, careful inquiry will disclose symptoms of some minor affection that will offer a satisfactory explanation for the onset or at least for the entrance of the infection.

The predilection of Hodgkin's disease to manifest itself primarily in an enlargement of the cervical glands led Trosseau to investigate all structures drained by these glands as possible portals of entry for infection. Murchison first directed attention to the tonsils which appear now to be the worst and most constant offenders. Not only may the disease be limited for a time to enlarged tonsils, as in a case reported by Delie,[19] and have a possible origin from a frank tonsillitis (Westphal), but it can affect these structures so slightly as to give no external evidence of abnormality. We have seen typical histologic Hodgkin's changes in tonsils which appeared normal clinically. Locating the disease in the tonsil is not sufficient, as this may be a secondary infection from other sources in the mouth and nasal passages. The possibility of carious teeth being portals of entry was recognized by Gowers. Rosenow has cultivated the *B. hodgkini* from peridental abscesses and sinuses.

In a fatal case with acute ethmoidal sinusitis, Bunting obtained this organism in pure culture from the affected cells. Organisms morphologically identical with those obtained in gland culture were found in smears made from secretions obtained from the upper nasal passages in a case in which the disease was present in the cervical glands. Chronic dacryocystitis, rhinitis, pharyngitis and otitis media are other lesions which have apparently been the starting point of the disease. We have seen two cases in which the portal of entry was certainly intestinal and others in which this was a possibility. In another the disease may have begun in the bronchial glands. Fraenkel and Much believe the infection may take place through the respiratory tract.

Preexisting adenitis has been noted frequently. Peacocke[20] observed the development of Hodgkin's disease in twin boys aged 4, both of whom had had measles complicated by adenitis. Other children in the same family had had measles but without adenitis. Delbet cites a case attributed to Billroth, in which the disease supervened on a lymphangitis and adenitis due to a bee sting. The possibility of this infection being added to a tuberculous adenitis has been mentioned above.

One patient with a primary enlargement of her inguinal glands had a profuse leukorrhea. Smears from the mucus from her cervical canal showed in considerable numbers an organism similar to that obtained in pure culture from an excised gland. Another had a sharp attack of cystitis preceding the onset, which is of greater significance since Fraenkel and Much observed an infiltration of ureter and bladder with Hodkgin's disease that they attributed to renal infection.

Skin lesions are fairly common. Fifteen per cent. of the cases studied by Westphal showed some skin affection and in 10 per cent. a lichen-like eruption preceded the onset. Trousseau's statement, so often repeated, that chronic irritations of the skin and mucous membrane may give access to a Hodgkin's infection, is evidently upheld. The site of the primary glandular enlargement would give a fairly definite regional location of the actual portal of entry.

The course of the disease depends on the relative virulence of the infection. In the acute forms death may result in a few (two to four) months; in the most chronic, life may be prolonged up to five years. A feeling of lassitude may precede recognition of the disease but more often the glandular enlargement is a fortuitous observation when the general health is good, notwithstanding there has been an absorption of sufficient toxin to alter the blood picture. During the early stage while the disease is localized in the primarily affected group of glands there is so little effect on the general health that proper attention is often neither sought nor given when it is sought. In acute cases there is a rapid transition into an intermediate stage where dissemination is manifest, physical and mental depression more constant and anemia, due to a toxic hemolysis, becomes evident. This transition into an intermediate stage in chronic cases is usually gradual and marked rather by the accidental discovery of additional glandular swellings more and more remote from those first affected. Exceptionally, following a period of chronicity there is a sudden explosive dissemination, after which a more acute course is run, suggesting a very rapid diminution in the powers of resistance of the individual. One of the most strikingly characteristic features of the disease, to be seen in the intermediate stage particularly but occurring if less obviously in the others, is the alternating periods of exacerbation and remission in the intensity of the process. During the periods of progression, the conditions manifested by the acute forms are simulated somewhat, there is more effect on the general health, the groups of glands become larger and the individual glands therein less differentiable and movable and a transient sensitiveness may develop. The overlying skin is less movable, may be boggy and even become reddened. These periods are relatively short and escape the notice of unobserving patients, though most all can recall the periods of remission when there is generally a marked diminution in size of the glandular tumors. This decrease in size may be so great and so persistent and so often accompanied by a sense of well-being that any treatment then in vogue, though the same improvement may be entirely spontaneous or follow an intercurrent acute infection, is apt to be considered causative, and another cure for Hodgkin's disease thereby discovered and unfortunately is usually promptly reported. Sooner or later another recrudescence appears, usually more vicious than those preceding, but now uncontrollable by the measures formerly so efficacious, and not infrequently introducing a rapid, final decline. Those later details, however, quite constantly escape publication.

During the intermediate stage extension takes place from one cervical triangle to the other, then to the neighboring axilla, the opposite side of the neck, the mediastinum, the opposite axilla, the spleen, the groins, the liver and retroperitoneal glands, in about that order. When the involvement has become widespread, the effects of increased intoxication and of pressure makes themselves evident in the terminal stage. Here is noted the grave anemia that may simulate the pernicious type, and the marked cachexia and emaciation, the tendency to purpura and to repeated hemorrhages from the mucous membranes due to a deficiency of blood platelets resulting from exhaustion of the bone marrow, febrile attacks, occasionally of the relapsing (Murchison) type, pleural and pericardial effusions, ascites, obstruction to blood and lymph circulation and to respiration. It is during this late stage that miliary tuberculosis so often develops and is unrecognized until revealed at necropsy.

[20] Peacocke: Tr. Roy. Acad. Med., Ireland, 1905, xiii, 1.

No description can be given of the nature and progress of the less common types of Hodgkin's disease that are not associated with glandular enlargements nor those varieties that are just beginning to be recognized as such through bacteriologic and hematologic methods.

DIAGNOSIS

It is impossible to escape a recognition of the very pronounced similarity between the clinical aspects of Hodgkin's disease and those of many malign neoplasms especially in the tendency to dissemination and to recurrences, and the ultimate general effects on the individual. In no disease is a prompt and particularly an early positive diagnosis of more consequence in successful treatment. This most important part of the therapeutic problem has, we believe, become relatively simple.

Without detracting in the least from the great importance of accurate history taking with its proper interpretation and a most thorough and complete examination,[21] these observations alone will not lead to an indisputably positive recognition of the disease, at least while a cure is still possible or probable. Final proof comes from the laboratory and there must be a competent objective observer who can recognize and construe slight variations, hematologic, bacteriologic and histologic. At the present time a satisfactory blood examination gives the most reliable immediate diagnostic evidence. Histologic studies cannot be equally positive until the early minute pathologic appearances of borderline affections are definitely established, granting that this may eventually be accomplished, and can never be possible in those less common types which do not manifest glandular swellings or easily accessible involvement in unimportant tissues. Nor can bacteriologic methods be uniformly satisfactory. Diphtheroid organisms are ubiquitous. Contaminations may occur under the most rigid technic, and more important still, the organism may take ten days to grow satisfactorily.

Material for histologic study can never, and for bacteriologic study, seldom, be obtained without the excision of a test gland or some affected tissue. Personal observations would have convinced us, even were the proof not clearly written in the reported experiences of all who have treated this disease, that partial excisions were accompanied by such actual and not hypothetic dangers of dissemination that "test excisions" are absolutely contraindicated unless the stage or the character of the disease is such that the only hope lies in vaccine therapy, should its value ever be undisputably established. Even under these conditions, using a polyvalent stock vaccine may be a safer method than taking some undue chances to obtain an autogenous culture.

Since Bonfils (1856) first pointed out that there was no increase in the white blood corpuscles in Hodgkin's disease and this fundamental observation was incorrect, it has been held that there are no characteristic blood changes in this affection, and that such as were observed marked either a secondary infection or a transition to lymphatic leukemia.

The essential features in the blood picture that have proved to be almost pathognomonic with but few conditions to be excepted, can be summarized briefly.[22]

There are two distinct types, an early and a late, showing a constant characteristic increase in the number of platelets (unless exhaustion of the bone marrow occurs) with abnormally large forms and either a relative or absolute increase in the so-called transitional cells. In the early type the leukocytes are usually less than ten thousand. Very early there is a moderate increase in the basophils, and when the disease is well established the eosinophils are slightly increased. The polymorphonuclear neutrophils remain within the usual limits, the lymphocytes at or slightly above the normal. The late type shows a leukocytosis which may reach one hundred thousand, the neutrophils are relatively increased to a percentage of from 75 to 92 and the lymphocytes are reduced to 5 per cent., frequently even less. The transitionals, the only other cells found in any numbers, are usually above 8 per cent. unless the leukocytosis is very high, when they may be relatively fewer, but still exceed the lymphocytes in number. This late picture is a result of the intensity of the disease rather than the extent of involvement and is usually largely dependent on duration for its development. Not only has this blood picture held clinically, having been confirmed in every instance either histologically or bacteriologically or both, but has appeared in monkeys inoculated with the living Hodgkin's bacillus and in one normal individual injected with the same, but killed, bacteria. Notably in one case of chloroma and two of so-called lymphosarcoma, the blood examination was positive and was confirmed by the cultivation of typical organisms from tissues that histologically alone might not have been properly diagnosed.

---

[21] A complete examination will determine the details of treatment and should include careful investigations by trustworthy specialists of the mouth, throat and nose, including the accessory sinuses, and may be satisfactorily conclusive only after skiagraphs have been made. No thoracic examination, however carefully done, is adequate until suitable roentgenograms have determined the absence of involved mediastinal glands or their size and location if present. When there is slight involvement in the anterior mediastinum, it is often unrecognizable by other methods, and this is especially true of the posterior which is invaded more frequently than is supposed. Moreover, this affords the only accurate method of gaging the efficacy of treatment even when the intrathoracic involvement is sufficient to be recognized by ordinary methods of examination. No great concern need be given to actual lung involvement as this is a manifestation of a late and probably a hopeless stage.

[22] It is quite probable that the reasons why these characteristic variations in the blood picture have so long escaped detection, depend on the technical methods followed in making and staining the blood smears and on the varying conceptions of the proper differentiation of the groups of leukocytes. Thus Litten is quoted by Fischer as having noted the platelet increase in 1895, an observation which Fischer attempted unsuccessfully to confirm, but which was upheld by Selenew who also remarked the very large forms. It remained for Bunting (Bull. Johns Hopkins Hosp., 1911, xxii, 114) to show the constancy and evident source of these structures in Hodgkin's disease. Lymphocytosis occurs and has been recognized by many observers, but is of little diagnostic importance since there is a constant and marked lymphopenia after the early stage. This was commented on by Steiger (Berl. klin. Wchnschr., 1913, i, 2129) who also repeated the old observation of a tendency to eosinophilia, which may be so high (over 20 per cent.) as to suggest the presence of some animal parasite and yet be due, as Lincoln's case has shown (Lincoln: Boston Med. and Surg. Jour., 1908, clvii, 677) entirely to an atypical manifestation of the disease. The leukocytosis which occurs in the late stages has been noted repeatedly.

Confusion has arisen so far in but one class of cases, those of tuberculous adenitis with an acute (coccal) secondary infection. Here, too, histologic and bacteriologic controls can fail to be conclusive. Differentiation from uncomplicated tuberculous adenitis is seldom difficult, the blood pictures are distinct and the reaction to tuberculin usually confirmatory. We have seen a positive von Pirquet reaction but four times. One patient had a clearly definite apical lesion, one, an adult with so-called lymphosarcoma, was without a demonstrable tuberculous focus, and the other two had preexisting tuberculous adenitis. In an acute case miliary tuberculosis was discovered post mortem and there had been a negative tuberculin test two months before. This man showed shortly before death a temporary transition to what is commonly accepted as a lymphatic leukemia blood count.

TREATMENT

However constant has been dispute as to the name or nature of the disease, there has ever been unanimous agreement that it was inevitably fatal in less than five years. Evidently, therefore, successful therapeutic measures would have to differ from any hitherto employed and must find their application in combating the various pathologic processes manifested as the disease progresses, while attempting at the same time to protect and enhance such curative physiologic reaction as could be recognized clinically and pathologically. Five years elapsed after our investigations began before the *B. hodgkini* was first isolated and its probable etiologic relationship established, so that we had opportunity to try other therapeutic methods than those dependent on a specific bacteriology. Our working hypothesis has been to accomplish (1) an exclusion of all possible liability to reinfection, hence a removal of the primary source of infection and its portal of entry; (2) the most rapid elimination of at least the major portion of the diseased tissue with the bacteria and toxins contained therein, in order to prevent further dissemination and to place the balance of power in favor of individual resistance, wherefore its surgical extirpation when conditions permitted; (3) a destruction of the remaining bacteria by any and every means, especially the Roentgen ray, hygiene, and more recently vaccine therapy has been employed; (4) the conversion into fibrous tissue by hygiene and the Roentgen ray of such irremovable abnormal tissue as cannot undergo resolution; (5) and finally, to continue treatment as circumstances seem to indicate until a clinical and roentgenologic examination and a normal blood picture indicate a cure has been of at least a year's duration.

The measures to be described hereafter have been found to give the best results, results so encouraging at present that their presentation seems to be justified. Every detail has been found to be of such importance that the reasons for the application of each will be given lest any be considered unessential and be slighted or discarded at the cost of the utmost possible prolongation of life and comfort of some individual. It should not be supposed that the procedures are equally applicable to all cases whatever be the stage of the disease or evident virulence of infection. Here again be it known that the extent of involvement is less significant than its location and nature, which can only be revealed by the detailed examination already outlined.

1. *Removal of the Source of Infection*—A. Where involvement is primarily cervical a complete pericapsular tonsillectomy in definitely and invariably indicated even if the tonsils appear perfectly normal. In addition the teeth, nose, ears, eyes and accessory structures must be excluded as the site of primary infection, or properly treated. B. If the primary glandular involvement is extracervical, a search must be made for a source of infection in the area thereby indicated and suspicious lesions treated appropriately. These measures should be instituted immediately and when possible carried out under local anesthesia, observing, so far as possible, the principles underlying the treatment of malignant tumors.

2. *Extirpation of the Major Portion of the Disease.* Excision of the cervical glands can be done as thoroughly as in the block dissection advocated by Crile, with the possible exception of preserving at least a part of the eleventh nerve and observing otherwise all of the precautions advocated by Halsted to safeguard dissemination. This can be accomplished without unduly reducing resistance, and we believe with less risk to the individual, than attempting to treat them otherwise. Any dissection less complete and careful is positively contraindicated.

The glands will be found to be more or less adherent, in some instances so adherent that their separation from the subclavian vein will be difficult, from the internal jugular so formidable, that this vein should be excised unless there be any question of the patency of its fellow. Glands adherent at the subclavian-jugular angle may be extremely trying to extirpate, but their removal is imperative in that this last source of mediastinal infection must be excluded. In spite of every effort we have cut the thoracic duct in two individuals. In one it was ligated, in the other the discharge of chyle was finally controlled by pressure. Neither manifested any ill effect.

The entire area exposed should be treated thoroughly and actively with full strength tincture of iodin and drained, as it is inconceivable that all contamination can be avoided. This additional irritant also increases the immediate inflammatory reaction, a very desirable feature, particularly as it has no effect on the ultimate functional or cosmetic result. Exposures of the entire wound area to the Roentgen ray should be started not later than the second day, preferably within a few hours of operation and continued at intervals of a few days to the limit of skin tolerance, for reasons that will be given later.

Such radical treatment will be criticized particularly by those wanting in surgical sympathy. In explanation be it known that any less thorough or even as thorough excision, without disinfection and subsequent radiation, may be followed by a recurrence, which, as Reed has reemphasized, can be more extensive than the original involvement. Recurrences in Hodgkin's disease are as little to be desired as in carcinoma. We have seen other glandular enlargements (for example, axillary, opposite cervical) begin their final decline *only after the removal* of this source of infection or drain on the powers of general resistance when the treatment was otherwise unchanged, just as we have seen some cervical enlargements permanently disappear under the Roentgen ray *after* tonsillectomy. These observations have been assumed to indicate that the balance of power has been changed and have been sufficiently numerous and well controlled to convince us that such treatment may determine the ultimate result no matter what other therapy is employed.

As yet we have not seen the same beneficent effect on mediastinal involvement, though apparently complete and final resolution has followed in axillary glands that have been probably, in size, at least, as extensively involved. The explanation seems to lie in the comparatively slight effect of the rays on intrathoracic tissue. Progress in intrathoracic involvement has been checked in two individuals if the radiographic evidence is conclusive. The general health has remained unimpaired in one boy for over six months and one girl appears radiantly healthy after four months, but in both the blood findings are ominous. Mediastinal infection may occur early or be absent even when both sides of the neck and both axillae have shown extensive enlargements for months. The appearance of intrathoracic involvement, in our experience, has been of more sinister significance than a moderate splenic or hepatic enlargement. Indeed, these may indicate, when other conditions are favorable, but an extensive reaction on the part of the defensive mechanism. Therefore we emphasize the extreme importance of protecting the mediastinum from any infection by extension from the neck or axilla, particularly before, but also even after intrathoracic involvement has occurred. We take this to mean that when the excision of the primarily affected cervical glands is not followed promptly by the progressive resolution of secondarily enlarged glands which may infect those in the mediastinum, that these glands also should be excised.

Axillary dissections should be as extensive and as thorough as the cervical. This requires division but not excision of the pectoralis major and resection of the minor. The nerves supplying the pectoralis major and the long thoracic nerve should be preserved. Involved glands have been found anterior to the major pectoral, between it and the minor and extending upward along the vein to the falciform ligament. An incision can be made along the anterior axillary line, extending thence if necessary a short distance along the lower margin of the clavicle that will give adequate exposure and not injure the breast tissue in women nor be cosmetically objectionable. Subsequent wound treatment should be the same as after cervical excisions.

No case in which the inguinal glands were affected primarily has come at a stage when radical extirpation was thought to have been indicated. The same general plan should be followed to protect the retroperitoneal as the intrathoracic lymphatics.

Patients presenting themselves in the later stages of the disease, with advanced involvement, intrathoracic or intraperitoneal or both, have been subjected to no radical treatment and this has probably been a mistake, at least in exceptional cases. Those in fairly good general condition and in whom the blood changes do not indicate the latest stage may be benefited materially by thus starting a regressive phase when other methods may help greatly. Without the initiative of this wave of regression those procedures have been futile. In one apparently hopeless case the patient has shown remarkable progress during the period between the excision of glands and the final preparation of her vaccine. This particular organism grew very reluctantly, and the excision removed considerable tissue from neck and groin because the periglandular adhesions made safer and easier the extirpation of groups of glands. Had she received any treatment in this interval there might be less justification in attributing some causal relationship to this excision.

3. *Destruction of Bacteria by the Roentgen Ray.*—No permanent cure has ever been obtained solely by the use of these rays. Numerous instances of marked improvement have been noted since the observations published by Senn.[23] Pfeiffer[24] made a very careful and extensive study of the value of Roentgen therapy in Hodgkin's disease and found the usual discouraging facts; after varying intervals of great improvement recurrences were inevitable and finally became uncontrollable. The reasons for its marked temporary efficacy have, to some extent, been discovered. A very resistant culture of *B. hodgkini* implanted on the most favorable mediums was destroyed by one exposure under conditions identical with the therapeutic dose, so long as these cultures were not much over 5 days old. Later than this the involution forms that develop so characteristically are more resistant, and after exposure to the ray the control subcultures were positive. This effect is not due to changes in the mediums, which after the same exposure supported subsequent cultures apparently equally well.

The patient from whose tissues the *B. hodgkini* was first grown in 1912, had, low in her right axilla, two glands a few inches apart. One was excised as a control. Cultures were positive, sections showed the usual moderately chronic process. The other gland was subjected to the usual radiotherapy and later excised.[25] Cultures this time were negative, when the technic had been developed so that positive cultures were being obtained constantly from tissue that was found histologically to show the disease. Comparison of the sections, which unfortunately were not stained and studied for the presence of bacteria, showed increased sclerosis, hyaline degeneration and an abundance of the "endothelioid" cells in excess of what could have been expected by natural reaction in the elapsed time. Moreover, there was present in the periglandular tissue, increase in fibrous elements as well as infiltration with round cells and neutrophils.

The effects of the ray immediately after operation are of the same character, only possibly less intense, than when given after excisions of malignant neoplasms with reflected skin flaps as advocated by Crile. There is a remarkable increase in the inflammatory reaction shown by the excessive serous exudate and superficial deposition of fibrin, the overlying skin is edematous and healing correspondingly delayed. After several months the evidences of the excess irritation disappear completely, the skin becomes soft and movable, pigmentation disappears, the scars of incisions are narrow and pale and there is a much reduced liability to keloidal changes.

Burns have resulted exceptionally and are probably not always to be avoided even under the most skilful administration and accurate dosage of the rays. We have been singularly fortunate in having the cooperaisms from tissues that histologically alone might not have been properly diagnosed.

[23] Senn: New York Med. Jour., 1903, lxxvii, 655.

[24] Pfeiffer: Beitr. z. klin. Chir., 1906, l, 277.

[25] Invaluable lessons were learned from this patient who, with the one exception noted below, is the last who has been subjected to meddlesome surgery. As a result of partial excisions the disease was so spread in the axilla as to demand a complete axillary dissection to protect the mediastinum, which has fortunately remained free.

Confusion has arisen so far in but one class of cases, those of tuberculous adenitis with an acute (coccal) secondary infection. Here, too, histologic and bacteriologic controls can fail to be conclusive. Differentiation from uncomplicated tuberculous adenitis is seldom difficult, the blood pictures are distinct and the reaction to tuberculin usually confirmatory. We have seen a positive von Pirquet reaction but four times. One patient had a clearly definite apical lesion, one, an adult with so-called lymphosarcoma, was without a demonstrable tuberculous focus, and the other two had preexisting tuberculous adenitis. In an acute case miliary tuberculosis was discovered post mortem and there had been a negative tuberculin test two months before. This man showed shortly before death a temporary transition to what is commonly accepted as a lymphatic leukemia blood count.

TREATMENT

However constant has been dispute as to the name or nature of the disease, there has ever been unanimous agreement that it was inevitably fatal in less than five years. Evidently, therefore, successful therapeutic measures would have to differ from any hitherto employed and must find their application in combating the various pathologic processes manifested as the disease progresses, while attempting at the same time to protect and enhance such curative physiologic reaction as could be recognized clinically and pathologically. Five years elapsed after our investigations began before the *B. hodgkini* was first isolated and its probable etiologic relationship established, so that we had opportunity to try other therapeutic methods than those dependent on a specific bacteriology. Our working hypothesis has been to accomplish (1) an exclusion of all possible liability to reinfection, hence a removal of the primary source of infection and its portal of entry; (2) the most rapid elimination of at least the major portion of the diseased tissue with the bacteria and toxins contained therein, in order to prevent further dissemination and to place the balance of power in favor of individual resistance, wherefore its surgical extirpation when conditions permitted; (3) a destruction of the remaining bacteria by any and every means, especially the Roentgen ray, hygiene, and more recently vaccine therapy has been employed; (4) the conversion into fibrous tissue by hygiene and the Roentgen ray of such irremovable abnormal tissue as cannot undergo resolution; (5) and finally, to continue treatment as circumstances seem to indicate until a clinical and roentgenologic examination and a normal blood picture indicate a cure has been of at least a year's duration.

The measures to be described hereafter have been found to give the best results, results so encouraging at present that their presentation seems to be justified. Every detail has been found to be of such importance that the reasons for the application of each will be given lest any be considered unessential and be slighted or discarded at the cost of the utmost possible prolongation of life and comfort of some individual. It should not be supposed that the procedures are equally applicable to all cases whatever be the stage of the disease or evident virulence of infection. Here again be it known that the extent of involvement is less significant than its location and nature, which can only be revealed by the detailed examination already outlined.

1. *Removal of the Source of Infection*—A. Where involvement is primarily cervical a complete pericapsular tonsillectomy in definitely and invariably indicated even if the tonsils appear perfectly normal. In addition the teeth, nose, ears, eyes and accessory structures must be excluded as the site of primary infection, or properly treated. B. If the primary glandular involvement is extracervical, a search must be made for a source of infection in the area thereby indicated and suspicious lesions treated appropriately. These measures should be instituted immediately and when possible carried out under local anesthesia, observing, so far as possible, the principles underlying the treatment of malignant tumors.

2. *Extirpation of the Major Portion of the Disease.* Excision of the cervical glands can be done as thoroughly as in the block dissection advocated by Crile, with the possible exception of preserving at least a part of the eleventh nerve and observing otherwise all of the precautions advocated by Halsted to safeguard dissemination. This can be accomplished without unduly reducing resistance, and we believe with less risk to the individual, than attempting to treat them otherwise. Any dissection less complete and careful is positively contraindicated.

The glands will be found to be more or less adherent, in some instances so adherent that their separation from the subclavian vein will be difficult, from the internal jugular so formidable, that this vein should be excised unless there be any question of the patency of its fellow. Glands adherent at the subclavian-jugular angle may be extremely trying to extirpate, but their removal is imperative in that this last source of mediastinal infection must be excluded. In spite of every effort we have cut the thoracic duct in two individuals. In one it was ligated, in the other the discharge of chyle was finally controlled by pressure. Neither manifested any ill effect.

The entire area exposed should be treated thoroughly and actively with full strength tincture of iodin and drained, as it is inconceivable that all contamination can be avoided. This additional irritant also increases the immediate inflammatory reaction, a very desirable feature, particularly as it has no effect on the ultimate functional or cosmetic result. Exposures of the entire wound area to the Roentgen ray should be started not later than the second day, preferably within a few hours of operation and continued at intervals of a few days to the limit of skin tolerance, for reasons that will be given later.

Such radical treatment will be criticized particularly by those wanting in surgical sympathy. In explanation be it known that any less thorough or even as thorough excision, without disinfection and subsequent radiation, may be followed by a recurrence, which, as Reed has reemphasized, can be more extensive than the original involvement. Recurrences in Hodgkin's disease are as little to be desired as in carcinoma. We have seen other glandular enlargements (for example, axillary, opposite cervical) begin their final decline *only after the removal* of this source of infection or drain on the powers of general resistance when the treatment was otherwise unchanged, just as we have seen some cervical enlargements permanently disappear under the Roentgen ray *after* tonsillectomy. These observations have been assumed to indicate that the balance of power has been changed and have been sufficiently numerous and well controlled to convince us that such treatment may determine the ultimate result no matter what other therapy is employed.

As yet we have not seen the same beneficent effect on mediastinal involvement, though apparently complete and final resolution has followed in axillary glands that have been probably, in size, at least, as extensively involved. The explanation seems to lie in the comparatively slight effect of the rays on intrathoracic tissue. Progress in intrathoracic involvement has been checked in two individuals if the radiographic evidence is conclusive. The general health has remained unimpaired in one boy for over six months and one girl appears radiantly healthy after four months, but in both the blood findings are ominous. Mediastinal infection may occur early or be absent even when both sides of the neck and both axillae have shown extensive enlargements for months. The appearance of intrathoracic involvement, in our experience, has been of more sinister significance than a moderate splenic or hepatic enlargement. Indeed, these may indicate, when other conditions are favorable, but an extensive reaction on the part of the defensive mechanism. Therefore we emphasize the extreme importance of protecting the mediastinum from any infection by extension from the neck or axilla, particularly before, but also even after intrathoracic involvement has occurred. We take this to mean that when the excision of the primarily affected cervical glands is not followed promptly by the progressive resolution of secondarily enlarged glands which may infect those in the mediastinum, that these glands also should be excised.

Axillary dissections should be as extensive and as thorough as the cervical. This requires division but not excision of the pectoralis major and resection of the minor. The nerves supplying the pectoralis major and the long thoracic nerve should be preserved. Involved glands have been found anterior to the major pectoral, between it and the minor and extending upward along the vein to the falciform ligament. An incision can be made along the anterior axillary line, extending thence if necessary a short distance along the lower margin of the clavicle that will give adequate exposure and not injure the breast tissue in women nor be cosmetically objectionable. Subsequent wound treatment should be the same as after cervical excisions.

No case in which the inguinal glands were affected primarily has come at a stage when radical extirpation was thought to have been indicated. The same general plan should be followed to protect the retroperitoneal as the intrathoracic lymphatics.

Patients presenting themselves in the later stages of the disease, with advanced involvement, intrathoracic or intraperitoneal or both, have been subjected to no radical treatment and this has probably been a mistake, at least in exceptional cases. Those in fairly good general condition and in whom the blood changes do not indicate the latest stage may be benefited materially by thus starting a regressive phase when other methods may help greatly. Without the initiative of this wave of regression those procedures have been futile. In one apparently hopeless case the patient has shown remarkable progress during the period between the excision of glands and the final preparation of her vaccine. This particular organism grew very reluctantly, and the excision removed considerable tissue from neck and groin because the periglandular adhesions made safer and easier the extirpation of groups of glands. Had she received any treatment in this interval there might be less justification in attributing some causal relationship to this excision.

3. *Destruction of Bacteria by the Roentgen Ray.*—No permanent cure has ever been obtained solely by the use of these rays. Numerous instances of marked improvement have been noted since the observations published by Senn.[23] Pfeiffer[24] made a very careful and extensive study of the value of Roentgen therapy in Hodgkin's disease and found the usual discouraging facts; after varying intervals of great improvement recurrences were inevitable and finally became uncontrollable. The reasons for its marked temporary efficacy have, to some extent, been discovered. A very resistant culture of *B. hodgkini* implanted on the most favorable mediums was destroyed by one exposure under conditions identical with the therapeutic dose, so long as these cultures were not much over 5 days old. Later than this the involution forms that develop so characteristically are more resistant, and after exposure to the ray the control subcultures were positive. This effect is not due to changes in the mediums, which after the same exposure supported subsequent cultures apparently equally well.

The patient from whose tissues the *B. hodgkini* was first grown in 1912, had, low in her right axilla, two glands a few inches apart. One was excised as a control. Cultures were positive, sections showed the usual moderately chronic process. The other gland was subjected to the usual radiotherapy and later excised.[25] Cultures this time were negative, when the technic had been developed so that positive cultures were being obtained constantly from tissue that was found histologically to show the disease. Comparison of the sections, which unfortunately were not stained and studied for the presence of bacteria, showed increased sclerosis, hyaline degeneration and an abundance of the "endothelioid" cells in excess of what could have been expected by natural reaction in the elapsed time. Moreover, there was present in the periglandular tissue, increase in fibrous elements as well as infiltration with round cells and neutrophils.

The effects of the ray immediately after operation are of the same character, only possibly less intense, than when given after excisions of malignant neoplasms with reflected skin flaps as advocated by Crile. 4. *Hygiene.*—Whatever treatment may be selected, evidently the native individual resistance will be the fundamental factor in determining the outcome. Nothing that will improve general physiologic efficiency should be omitted as everything should be that might provoke physiologic deficiency. In this connection may be considered the question of drugs. Tonics are often indicated. Arsenic is no more specific than iron. The uses of maximum doses of Fowler's solution internally, subcutaneously or injected directly into the affected glands has been wondrously exploited. Its value is not more than transient. Marked and prompt improvement has followed the administration of salvarsan intramuscularly and intravenously, as in a case treated by Galland,[26] another treated by Dr. L. F. Barker (personal communication) and in one of our series, but these effects are only fleeting and when recrudescence appears it is unaffected by further administration of this remedy. No indication has been found for the use of benzol (benzene C_6H_6). The treatment of one case by this means has been recorded,[27] but the diagnosis was not established and only the early results were reported.

The mixed toxins of erysipelas and *Bacillus prodigiosus* so warmly and authoritatively advocated by Coley have not been tried, in spite of the knowledge that almost complete if temporary disappearance of glandular swellings has followed acute intercurrent infections, notably in one rather advanced case after a severe scarlatina. The belief that Hodgkin's disease was an inflammation, and a disinclination to add to the intoxication in view of the lack of evidence that any permanent benefit has thus been obtained, even in Coley's cases,[28] was considered sufficiently contraindicative. In a personal communication Dr. Coley has stated that a patient under the care of a former assistant was treated in the Ottawa hospital and has remained well for six years.[29] In this instance, while the clinical diagnosis appeared probable it was not confirmed pathologically and must therefore be, to some extent, questionable.

5. *Vaccines.*—Successful active or passive immunization in the light of the constant failures that have followed all other therapeutic methods, has been a stimulating hypothetic possibility. Encouraging results are not wanting, neither are the discouraging, at least so far as vaccination is concerned. Improvement has followed subcutaneous injections of both polyvalent stock vaccines and the autogenous, but not in every case, and in some at least, the same old discouraging sequence of events ensues and subsequently an uncontrollable recrudescence leading rapidly to death gives the impression that history is repeating itself and that another "cure" may have to be admitted to the list of failures.

In no case that we have seen treated by vaccination has there been a favorable result in the rapidity, extent or permanence of improvement that has not been equalled at least by observations on similar cases treated essentially similarly except for the vaccine administration.

One boy whose history will be given has had vaccine treatment over a period of two months for a slight mediastinal involvement, the only discoverable manifestation of a recurrence. Stock vaccines prepared by Dr. Rosenow, who generously forwarded an adequate supply, and by Dr. Clara Moore at the University of Wisconsin according to Dr. Rosenow's directions, have been given at five-day intervals, to the total number of 62,000 million bacilli. There has never been a local or general reaction and his health has remained good. The involvement has remained stationary but in addition he has been receiving the Roentgen ray in maximum doses. His blood is beginning to show features of the late stage.

Another patient, whose history also will be given, had, in addition to extensive mediastinal involvement, a small group of involved glands in her right axilla. She received subcutaneously over a period of four months 18,000 million bacilli of an autogenous vaccine. There was improvement in her general health, increase in weight, but not more than could have resulted without the use of vaccines. No marked general reactions resulted at any time, though subcutaneous nodular induration appeared at the sites of the injections. Roentgenographic and physical examinations showed no diminution in the mediastinal disease and her blood picture remained unchanged. It became essential to know what had occurred in the axillary glands as they had not changed noticeably in size or consistency. A partial excision was done and the glands were removed, followed by the maximum doses of the Roentgen ray which had not hitherto been given at this area. These glands were not manifestly different microscopically or macroscopically from those obtained from her opposite cervical region, three months before; in fact, the microscopic pictures were virtually identical.

There is no desire to detract from the possible value of vaccine therapy in Hodgkin's disease, but such observations as we have been able to make, and every effort to obtain proper controls and to maintain an objective point of view has been exerted, will permit of not more than a Scotch verdict. Vaccination in our hands cannot be shown as yet to have exerted marked if any influence on the ultimate course of the disease, but admittedly it is too soon to pass final judgment. If there is an ideal method of vaccination for Hodgkin's disease we believe it is yet to be established.

6. *Conversion of Abnormal Tissue into Fibrous Tissue.*—This is desirable when resolution is impossible, in order to remove any tendency to pressure effects and the liability to subsequent infections, of whatever nature, in structures of abnormal powers of resistance. Conversion into fibrous tissue by no means indicates that such accumulations will be permanent. It is quite probable that when this dense abnormal tissue is not subjected to constant physiologic strain it undergoes some form of degeneration leading to ultimate absorption as seen for example in certain types of pancreatitis and intra-abdominal adhesions. The best possible physical condition and Roentgen rays are the only methods that have been supposed to aid this transformation.

SUPPLEMENTARY TREATMENT

It has been so well established that patients may be apparently well and remain so even up to five years, only to succumb to an acute, explosive recrudescence, that there is positive indication for prolonged aftertreatment, periodically repeated. The exceeding importance of protecting the general health cannot be overstated. Periods of even slight mental and physical depression have preceded, if they have not introduced, recrudescences. Except in two cases, in which the blood picture returned to normal and has remained there, we have not seen a single instance in which this evidence of a persistence of the infection was eliminated. Routine blood examinations are made as the patients report for observation, either at stated intervals of a few months or whenever untoward symptoms are suspected. The blood count has been found to give the earliest and surest evidence of an impending recrudescence or of the persistence of some focus of infection that had escaped detection. Apparently, recurrences of the disease, if taken very early, may be controlled by appropriate measures, whereas, if the infection increases to any extent in virulence the characteristic rapid fatal progress is to be expected.

REEXCISIONS

Glandular recurrences have shown two types. One that follows soon after incomplete excision is of the softer, more cellular and acute variety. The other appears at a longer interval, perhaps more than a year after complete excision and repeated courses of the Roentgen ray, and is more chronic in every way, yet reexcisions usually done under local anesthesia have produced improvement, local and general, otherwise unobtainable. Removal of early recurrences is at times justifiable, but seldom is to be expected to help materially and has led to the opinion expressed by Fischer that reexcisions are always unwarranted.

During the period of quiescence, when there is no longer any external evidence of the disease, should be the time, hypothetically at least, when the administration of vaccine virtually prophylactically might be expected to be of the greatest benefit. Under such conditions the only judgment as to immediate improvement would have to be based on blood changes, and as the vaccine itself affects the blood picture nothing definite can as yet be stated. There has been no improvement noted in the return toward normal; either there has been no change or there was evidence of some degree of unfavorable variation.

One must constantly bear in mind that the safety of these patients lies in unremitting watchfulness and attention to details. The fact that otherwise there must be a certain fatality should lead to persistence to find the therapeutic measures indicated and give one courage to put them to practice.

RESULTS

A cure or, better, a recovery can be considered as established only when there is no trace of the disease, including a normal blood picture, at least five years after the last manifestation of the infection. Recrudescence has occurred after a shorter period of apparent freedom. A case recorded by Eve,[30] had an interval of six years between a primary operation and the first recurrence but the diagnosis was not established.

THE BEGINNING OF SYPHILIS*

W. A. PUSEY, M.D.
CHICAGO

> "By the historical method alone can many problems in medicine be approached properly. For example, the student who dates his knowledge of tuberculosis from Koch may have a very correct, but a very incomplete, appreciation of the subject. Within a quarter of a century our libraries will have certain alcoves devoted to the historical consideration of the great diseases, which will give to the student that mental perspective which is so valuable an equipment in life."
> —*Osler.*

The history of syphilis is unique among the records of great diseases. For, unlike most diseases, it does not gradually emerge into the historical records of medicine as its characters become recognized, but appears on the stage of history with a dramatic suddenness in keeping with the tragic reputation it has made—as a great plague sweeping within a few years over the known world. Syphilis is the one disease whose history begins with a definite date. That date is the date of the discovery of America. It happens also that the ten years from 1903 to 1913 were fruitful of discoveries of such fundamental importance in syphilis that they represent an epoch—the most important epoch—in the history of our knowledge of the disease.

LACK OF KNOWLEDGE OF SYPHILIS AMONG THE ANCIENTS

Local genital diseases have been recognized from ancient times; references to them are numerous in both Occidental and Oriental literature. It is, however, a very striking fact that in all medieval and ancient literature, although sexual matters are favorite topics and are considered frequently and with freedom, there is no reference to a disease of the genitals which is followed by constitutional symptoms. Many diseases involving the skin are easily recognized in the descriptions of medieval and classical literature, but in spite of the most painstaking and zealous searching of all literary evidence, no single authentic document has been found in ancient literature in which a description of syphilis can be recognized. Prior to the last years of the fifteenth century no description of the syphilitic syndrome existed.

THE EPIDEMIC OF SYPHILIS AT THE END OF THE FIFTEENTH CENTURY

In the autumn of 1494, Charles VIII of France, with an army composed of mercenaries from all parts of western Europe, invaded Italy for the conquest of Naples. Italy, which at this time had reached the height of effeminate luxury and was weakened by the rivalries of her numerous states, was able to make no effective resistance to the well-organized forces of Charles; and the progress of his army through the peninsula was more of a triumphal march of debauchery than a serious military campaign. Charles was able to make good his claims to the throne of Naples and to set up his court for permanent occupation. In a short time, however, his army became so tion of exceptionally competent therapeutic roentgenologists who will subsequently make a formal report of their work and observations. It is a pleasant duty to acknowledge an indebtedness to Dr. Foerster and Dr. Baer for their unflagging interest in our work and generous care of these patients, but particularly for having proved the value of this phase of treatment, possibly as important as any other detail, when given rationally as to time, place and method.

---

* This article is the first chapter of a monograph on "Syphilis," being one part of a volume, now on the press of the American Medical Association, commemorating the completion of the Panama Canal and reflecting what medicine has done to make the canal possible. The article on Typhus Fever by Vaughan, published May 29, 1915, was part of a monograph on "Infection and Immunity," also to be included in this book. *The other articles contained in this "Commemoration Volume"* are by Drs. W. J. Mayo, Simon Flexner, E. O. Jordan, Major General Gorgas and Mr. F. L. Hoffman. The book, of some 380 pages, will be issued about July 1. Price, $2.50.

4. *Hygiene.*—Whatever treatment may be selected, evidently the native individual resistance will be the fundamental factor in determining the outcome. Nothing that will improve general physiologic efficiency should be omitted as everything should be that might provoke physiologic deficiency. In this connection may be considered the question of drugs. Tonics are often indicated. Arsenic is no more specific than iron. The uses of maximum doses of Fowler's solution internally, subcutaneously or injected directly into the affected glands has been wondrously exploited. Its value is not more than transient. Marked and prompt improvement has followed the administration of salvarsan intramuscularly and intravenously, as in a case treated by Galland,[26] another treated by Dr. L. F. Barker (personal communication) and in one of our series, but these effects are only fleeting and when recrudescence appears it is unaffected by further administration of this remedy. No indication has been found for the use of benzol (benzene C_6H_6). The treatment of one case by this means has been recorded,[27] but the diagnosis was not established and only the early results were reported.

The mixed toxins of erysipelas and *Bacillus prodigiosus* so warmly and authoritatively advocated by Coley have not been tried, in spite of the knowledge that almost complete if temporary disappearance of glandular swellings has followed acute intercurrent infections, notably in one rather advanced case after a severe scarlatina. The belief that Hodgkin's disease was an inflammation, and a disinclination to add to the intoxication in view of the lack of evidence that any permanent benefit has thus been obtained, even in Coley's cases,[28] was considered sufficiently contraindicative. In a personal communication Dr. Coley has stated that a patient under the care of a former assistant was treated in the Ottawa hospital and has remained well for six years.[29] In this instance, while the clinical diagnosis appeared probable it was not confirmed pathologically and must therefore be, to some extent, questionable.

5. *Vaccines.*—Successful active or passive immunization in the light of the constant failures that have followed all other therapeutic methods, has been a stimulating hypothetic possibility. Encouraging results are not wanting, neither are the discouraging, at least so far as vaccination is concerned. Improvement has followed subcutaneous injections of both polyvalent stock vaccines and the autogenous, but not in every case, and in some at least, the same old discouraging sequence of events ensues and subsequently an uncontrollable recrudescence leading rapidly to death gives the impression that history is repeating itself and that another "cure" may have to be admitted to the list of failures.

In no case that we have seen treated by vaccination has there been a favorable result in the rapidity, extent or permanence of improvement that has not been equalled at least by observations on similar cases treated essentially similarly except for the vaccine administration.

One boy whose history will be given has had vaccine treatment over a period of two months for a slight mediastinal involvement, the only discoverable manifestation of a recurrence. Stock vaccines prepared by Dr. Rosenow, who generously forwarded an adequate supply, and by Dr. Clara Moore at the University of Wisconsin according to Dr. Rosenow's directions, have been given at five-day intervals, to the total number of 62,000 million bacilli. There has never been a local or general reaction and his health has remained good. The involvement has remained stationary but in addition he has been receiving the Roentgen ray in maximum doses. His blood is beginning to show features of the late stage.

Another patient, whose history also will be given, had, in addition to extensive mediastinal involvement, a small group of involved glands in her right axilla. She received subcutaneously over a period of four months 18,000 million bacilli of an autogenous vaccine. There was improvement in her general health, increase in weight, but not more than could have resulted without the use of vaccines. No marked general reactions resulted at any time, though subcutaneous nodular induration appeared at the sites of the injections. Roentgenographic and physical examinations showed no diminution in the mediastinal disease and her blood picture remained unchanged. It became essential to know what had occurred in the axillary glands as they had not changed noticeably in size or consistency. A partial excision was done and the glands were removed, followed by the maximum doses of the Roentgen ray which had not hitherto been given at this area. These glands were not manifestly different microscopically or macroscopically from those obtained from her opposite cervical region, three months before; in fact, the microscopic pictures were virtually identical.

There is no desire to detract from the possible value of vaccine therapy in Hodgkin's disease, but such observations as we have been able to make, and every effort to obtain proper controls and to maintain an objective point of view has been exerted, will permit of not more than a Scotch verdict. Vaccination in our hands cannot be shown as yet to have exerted marked if any influence on the ultimate course of the disease, but admittedly it is too soon to pass final judgment. If there is an ideal method of vaccination for Hodgkin's disease we believe it is yet to be established.

6. *Conversion of Abnormal Tissue into Fibrous Tissue.*—This is desirable when resolution is impossible, in order to remove any tendency to pressure effects and the liability to subsequent infections, of whatever nature, in structures of abnormal powers of resistance. Conversion into fibrous tissue by no means indicates that such accumulations will be permanent. It is quite probable that when this dense abnormal tissue is not subjected to constant physiologic strain it undergoes some form of degeneration leading to ultimate absorption as seen for example in certain types of pancreatitis and intra-abdominal adhesions. The best possible physical condition and Roentgen rays are the only methods that have been supposed to aid this transformation.

SUPPLEMENTARY TREATMENT

It has been so well established that patients may be apparently well and remain so even up to five years, only to succumb to an acute, explosive recrudescence, that there is positive indication for prolonged after-treatment, periodically repeated. The exceeding importance of protecting the general health cannot be overstated. Periods of even slight mental and physical depression have preceded, if they have not introduced, recrudescences. Except in two cases, in which the blood picture returned to normal and has remained there, we have not seen a single instance in which this evidence of a persistence of the infection was eliminated. Routine blood examinations are made as the patients report for observation, either at stated intervals of a few months or whenever untoward symptoms are suspected. The blood count has been found to give the earliest and surest evidence of an impending recrudescence or of the persistence of some focus of infection that had escaped detection. Apparently, recurrences of the disease, if taken very early, may be controlled by appropriate measures, whereas, if the infection increases to any extent in virulence the characteristic rapid fatal progress is to be expected.

REEXCISIONS

Glandular recurrences have shown two types. One that follows soon after incomplete excision is of the softer, more cellular and acute variety. The other appears at a longer interval, perhaps more than a year after complete excision and repeated courses of the Roentgen ray, and is more chronic in every way, yet reexcisions usually done under local anesthesia have produced improvement, local and general, otherwise unobtainable. Removal of early recurrences is at times justifiable, but seldom is to be expected to help materially and has led to the opinion expressed by Fischer that reexcisions are always unwarranted.

During the period of quiescence, when there is no longer any external evidence of the disease, should be the time, hypothetically at least, when the administration of vaccine virtually prophylactically might be expected to be of the greatest benefit. Under such conditions the only judgment as to immediate improvement would have to be based on blood changes, and as the vaccine itself affects the blood picture nothing definite can as yet be stated. There has been no improvement noted in the return toward normal; either there has been no change or there was evidence of some degree of unfavorable variation.

One must constantly bear in mind that the safety of these patients lies in unremitting watchfulness and attention to details. The fact that otherwise there must be a certain fatality should lead to persistence to find the therapeutic measures indicated and give one courage to put them to practice.

RESULTS

A cure or, better, a recovery can be considered as established only when there is no trace of the disease, including a normal blood picture, at least five years after the last manifestation of the infection. Recrudescence has occurred after a shorter period of apparent freedom. A case recorded by Eve,[30] had an interval of six years between a primary operation and the first recurrence but the diagnosis was not established.

THE BEGINNING OF SYPHILIS *

W. A. PUSEY, M.D.

CHICAGO

> "By the historical method alone can many problems in medicine be approached properly. For example, the student who dates his knowledge of tuberculosis from Koch may have a very correct, but a very incomplete, appreciation of the subject. Within a quarter of a century our libraries will have certain alcoves devoted to the historical consideration of the great diseases, which will give to the student that mental perspective which is so valuable an equipment in life."
> —*Osler.*

The history of syphilis is unique among the records of great diseases. For, unlike most diseases, it does not gradually emerge into the historical records of medicine as its characters become recognized, but appears on the stage of history with a dramatic suddenness in keeping with the tragic reputation it has made—as a great plague sweeping within a few years over the known world. Syphilis is the one disease whose history begins with a definite date. That date is the date of the discovery of America. It happens also that the ten years from 1903 to 1913 were fruitful of discoveries of such fundamental importance in syphilis that they represent an epoch—the most important epoch—in the history of our knowledge of the disease.

LACK OF KNOWLEDGE OF SYPHILIS AMONG THE ANCIENTS

Local genital diseases have been recognized from ancient times; references to them are numerous in both Occidental and Oriental literature. It is, however, a very striking fact that in all medieval and ancient literature, although sexual matters are favorite topics and are considered frequently and with freedom, there is no reference to a disease of the genitals which is followed by constitutional symptoms. Many diseases involving the skin are easily recognized in the descriptions of medieval and classical literature, but in spite of the most painstaking and zealous searching of all literary evidence, no single authentic document has been found in ancient literature in which a description of syphilis can be recognized. Prior to the last years of the fifteenth century no description of the syphilitic syndrome existed.

THE EPIDEMIC OF SYPHILIS AT THE END OF THE FIFTEENTH CENTURY

In the autumn of 1494, Charles VIII of France, with an army composed of mercenaries from all parts of western Europe, invaded Italy for the conquest of Naples. Italy, which at this time had reached the height of effeminate luxury and was weakened by the rivalries of her numerous states, was able to make no effective resistance to the well-organized forces of Charles; and the progress of his army through the peninsula was more of a triumphal march of debauchery than a serious military campaign. Charles was able to make good his claims to the throne of Naples and to set up his court for permanent occupation. In a short time, however, his army became so weakened through disease and dissipation that the Neapolitans were able to assert themselves and drive it out. The retreat of Charles and his soldiers from Italy in the summer of 1495 was little better than a rout, and the various troops were left ultimately to return to their countries in their own disorganized way.

---

* This article is the first chapter of a monograph on "Syphilis," being one part of a volume, now on the press of the American Medical Association, commemorating the completion of the Panama Canal and reflecting what medicine has done to make the canal possible. The article on Typhus Fever by Vaughan, published May 29, 1915, was part of a monograph on "Infection and Immunity," also to be included in this book. The other articles contained in this "Commemoration Volume" are by Drs. W. J. Mayo, Simon Flexner, E. O. Jordan, Major General Gorgas and Mr. F. L. Hoffman. The book, of some 380 pages, will be issued about July 1. Price, $2.50.

THE BEGINNING OF THE EPIDEMIC

All contemporaneous records are at one in attributing the epidemic of syphilis which began in Italy at this time to Charles' army, and the quick spread of the disease over Europe to the scattering of his troops. Syphilis, if it existed before this time, was unrecognized. It was at the appearance of this great epidemic that physicians and laymen alike became aware of a disease of the genitals, which was followed by constitutional symptoms and of which they had no previous experience.

THE SPREAD OF SYPHILIS OVER EUROPE

The development of syphilis in Italy can be traced in the local chronicles of the time step by step with the progress of Charles' army, and with the scattering of his soldiers it went over western Europe in a rapid-spreading epidemic. It appeared in France and Germany and Switzerland in 1495, in Holland and Greece in 1496. It spread to England and Scotland in 1497; to Hungary and Russia in 1499.

Iwan Bloch, to whom all students are indebted for bringing together the known facts concerning the early history of syphilis, gives many contemporaneous references testifying to the interest excited by the new disease and to the importance attached to it. Thus, in 1496, the Parliament of Paris decreed that all persons infected with the disease should leave the city within twenty-four hours. In 1496-1497 prophylactic measures against the disease were attempted at Nürnberg. On April 21, 1497, the town council of Aberdeen, Scotland, ordered that, for protection from the disease which had come out of France and strange parts, all light women desist from their vice and sin of venery and work for their support, on pain, else, of being branded with a hot iron on their cheek and banished from the town. Six months after the Aberdeen order, the Scottish Privy Council passed an edict ordering all inhabitants of Edinburgh afflicted with syphilis into banishment to the island of Inchkeith near Leith. In 1496, Grünpeck, a German writer, mentions that English soldiers in Italy had acquired syphilis. The archives of Bristol indicate that the disease was introduced there in 1498 from Bordeaux, and hence was called the Bordeaux disease. In the Breviarie of Health, by Andrew Boorde, published in 1575, it is stated that "In English Morbus Gallicus is called the French pocks, and when that I was young they were named the Spanish pocks."

Indeed this tendency to shift the responsibility for the disease on others by giving it their name, appears all through the early references to it. The Italians called it the Spanish or the French disease; the French called it the Italian disease; the English called it the French disease; the Russians called it the Polish disease; the Turks called it the French disease; the Indians and the Japanese called it the Portuguese disease. And, as we shall see, the first Spaniards who recognized the disease called it the disease of Española, which meant at that time the disease of Haiti.

ITS SPREAD TO THE ORIENT

In quick sequence the disease spread over the rest of the known world, carried by the great voyagers of that period. The Portuguese soon carried it to Africa and the Orient. The researches of Okamura and Susuki for Japan and China, and those of Jolly and others for India, show the introduction of syphilis into these countries only after contact with Europe. The Indian, Chinese and Japanese languages had no native names for the disease, and, like the Europeans, the Orientals gave it names indicating its foreign origin. In India the disease was first recognized in 1498, after the arrival of Vasco de Gama, who had left Portugal in 1497. It appeared in Canton, China, in 1905, after the visit of Europeans. It was not recognized in Japan until 1569, when its appearance at Nagasaki was attributed to Chinese or Portuguese sailors.

There is thus an accurate historic record of the startling spread of syphilis over the known world in a few years after 1495; and from that time it has everywhere been endemic. No similar record exists of the sudden establishment of any other great disease among the larger part of the earth's inhabitants.

THE SEVERITY OF THE FIRST EPIDEMIC

The early recognition of syphilis and the prompt record of its spread over the civilized world are to be accounted for not so much by its newness, although it was everywhere recognized as a new disease, as by its severity. It amounts almost to an axiom in pathology that when an infectious disease first appears among a people—finds lodgment in a virgin soil—it rages with unwonted severity. This has been noted many times—with measles, scarlet fever, smallpox, and with syphilis in modern epidemics among isolated peoples. And this was a characteristic of the great epidemic of syphilis which occurred at the end of the fifteenth century.

In syphilis as ordinarily seen, its early manifestations are trivial in character, so trivial in fact that they are dangerously deceptive to the careless. The symptoms are mild and the patients are not acutely ill. All evidence, however, points to the severe character of the disease during this first epidemic. The cases ran an acute febrile course accompanied by symptoms of such severity as are now seen only in very unusual cases. There were high fever, intense headache and bone and joint pains; early skin symptoms so severe that they simulated smallpox; great prostration, and very frequently a fatal ending early in the disease, a result that is the rarest occurrence at present. This epidemic had all the characteristics of a virulent plague. With the loose morals of the time, however, syphilization of the world was rapid, and contemporaneous evidence, Fracastoro for example, indicates that the severity of the symptoms of early syphilis rapidly diminished; and within fifty years the disease had assumed the character with which the world has since been familiar.

EARLY SPECULATION AS TO ITS ORIGIN

The origin of syphilis was, at the time of this great epidemic and until recently has still been, a subject of much speculation and discussion. In keeping with man's superstitions, particularly at the time of the appearance of syphilis, it has been attributed to every imaginable source; to vice and sin, and the anger of

Providence; to dirt and beasts; to the elements and the influence of the heavenly bodies. Much unsuccessful effort was made to demonstrate its presence in Europe in the middle ages and earlier, although contemporaneous opinion pointed to the Spaniards and Americans for its origin. Later, as the disease became familiar and men lost sight of its sudden appearance, opinion veered round to the view that it had always existed in Europe. It is only within the last thirty years that its American origin has been practically demonstrated.

THE EVIDENCE OF ITS AMERICAN ORIGIN

The bald fact of the sudden appearance of syphilis shortly after the return of Columbus from his first voyage might easily suggest and lend plausibility to the theory of the American origin of the disease. The presence of Spanish adventurers in Charles' army would furnish the connecting link between Barcelona and Seville and Columbus' crew and the Italian epidemic. But in addition to the chronologic sequence of Columbus' return from America and the first recognized epidemic of syphilis in Europe, there are numerous other facts which confirm the American theory of its origin.

As we have seen, certain of these facts stand out prominently in the great epidemic:

The disease at the time was recognized as a new disease.

Names for it did not exist, and as it spread over Europe, men were hard put to give it a designation. The same was true on its appearance in the Orient.

The development of the great epidemic was definitely associated with the Italian campaign of Charles VIII, and its rapid spread over Europe was associated with the breaking up of his army. Its origin was recognized as being southwestern Europe. Even with the first outbreak in Italy, Spain was pointed to as the country whence it came, and the Spanish soldiers of Charles' army were incriminated as the authors of its distribution.

The disease pursued a course of unusual severity and spread over Europe with the rapidity of an infectious disease among people unprotected by any previous infection with it.

ABSENCE OF EVIDENCE IN EARLY EUROPEAN BONES

Parallel with the absence of any pre-Columbian documentary evidence of the existence of syphilis, is the absence of any evidence of syphilis in pre-Columbian European or Oriental bones. Bones withstand time, and the ravages of many diseases can be clearly traced in ancient bones that have come down to us. Syphilis is one of the diseases which leaves frequent, unmistakable evidence of its existence in bones; and if syphilis existed in Europe before the discovery of America it would be expected that evidence of it would be abundantly found in the great collections of prehistoric, ancient and medieval bones that exist. With the licentiousness of Rome and of the Dark Ages, syphilis would have been expected to leave a broad trail in the bony remains of those times; and yet careful scrutiny of those bones has failed to reveal any evidence of it. Most of the great European collections of human skeletons of pre-Columbian times have been carefully examined with this point in view, without the finding of a single syphilitic bone, and no less an authority than Virchow, one of the world's greatest anthropologists and probably its greatest pathologist, has declared that no pre-Columbian bone has been produced presenting evidence of syphilis. On the other hand, human skeletons of later date showing syphilitic changes have been found in all parts of the world.

AMERICAN PREHISTORIC BONES

On the other side it must be said that we have no unquestionable evidence of syphilis in pre-Columbian bones in America. Syphilitic bones have been found in North and South and Central America, and the presumption is strong that some of these bones are of pre-Columbian origin. Nevertheless, the difficulty in establishing the antiquity of Indian remains is so great that the pre-Columbian origin of these bones cannot be demonstrated.

SPANISH DOCUMENTARY EVIDENCE

But quite apart from this circumstantial evidence of the American origin of syphilis, there has been discovered in recent times definite documentary evidence indicating the introduction of syphilis into Spain by the sailors of Columbus' first voyage. For the unearthing of this evidence we are indebted to Montejo y Robledo, a Spanish army surgeon, who critically examined all the early Spanish sources and reported his findings at the fourth Congreso internacional de Americanistas, at Madrid in 1882. The importance of Montejo's work was overlooked until attention was called to it by Seler in 1895.

Ruy Dias de Isla.—The most important evidence produced by Montejo—and surprisingly definite evidence it is—is the account of syphilis of Ruy Dias de Isla. To paraphrase Bloch: at the time of the first appearance of syphilis in Europe, Dias de Isla was a physician of note, who for ten years held the position of surgeon at the Hospital of All Saints in Lisbon. There he had a large experience in syphilis, which he incorporated in a special work which was published between 1510 and 1520, and was fortunately discovered by Montejo in the National Library of Madrid. Dias de Isla is known to have been in practice in 1493 in Barcelona, and he was thus in a position to be a witness to the very landing of syphilis in Europe. The title of Dias' book put into English is: "Treatise, entitled, Fruit of All Saints against the Disease of the Island Española, by Master Rodrigo de Isla, Surgeon and Citizen of Lisbon, to the Common and General Good of those Suffering from the Disease in Question, Commonly Called Bubas." The contents of the book are, briefly, as follows: Syphilis was unknown before the year 1493. It was brought by the crew of Columbus on his first voyage from Española, or Haiti. Dias called it the disease of the Island of Española, but also gave a number of native names for the disease. A majority of Columbus' crew returned to Spain infected with syphilis, and Dias himself treated several syphilitic sailors from this squadron, among them the pilot, Pinzon of Palos.

Oviedo, Las Casas, and the Spanish Chroniclers.—This record of Dias de Isla is corroborated by other contemporary Spanish chroniclers; particularly by the important works of Oviedo, and of the great Las Casas, both of whom were in America within a few years after its discovery. Oviedo was in Barcelona at the return of Columbus in 1493, and knew Columbus and members of his crew. In his "Historia general y natural de las Indias," and in a report drawn up at the command of Charles V of Spain, he recites: That the disease was contracted from Indian women by the Spaniards with Columbus; that it was brought by them to Spain and thus transmitted to the army of Charles VIII by Spanish soldiers; and that syphilis should be called the West Indian disease, rather than the French or Neapolitan disease. He also mentions in independent corroboration of Dias de Isla, that one of the brothers, Pinzon, contracted the disease, and that it "is common among the Indians, but in those regions is not so dangerous as with us."

Oviedo was an advocate for Spain, and it has been urged that the theory of the Indian origin of syphilis may have been readily adopted by him in his attempts to palliate the cruelty of the Spaniards toward the Indians. No such charge, however, will stand against Las Casas, whose efforts were all in behalf of the Indians, but who, nevertheless, did not hesitate to give in detail the facts of syphilis among them.

The father of Las Casas accompanied Columbus on his second voyage, and Las Casas himself was in Haiti in 1498, where he lived many years and wrote his "Historia general de las Indias." He records: "There were, and still are, two things which at the beginning were very dangerous to the Spaniards. One is the disease syphilis, which in Italy is known as the French evil. . . ."

"It is, however, known for certain that it came from this island, either when, with the return of the Admiral Don Christóbal Cólon with the news of the discovery of the West Indies, the first Indians arrived, whom I saw myself in Seville, or it may be that certain Spaniards were already tainted with this disease at the time of their first return to Castile. . . ."

"I took the trouble on several occasions to interrogate the Indians of this island as to whether this disease was of great antiquity, and they answered, 'Yes.'" . . .

"It is also an undoubted fact that all Spaniards addicted to sexual excess, who did not in this island observe the virtue of continence, were attacked by the disease, not one in a hundred escaping, unless the woman was healthy." He too emphasizes the greater severity of the disease among the Spaniards than among the natives.

In addition to Oviedo and Las Casas, numerous others of the early chroniclers of Spanish America (Pane, Sahagun, Hernandez), testify as shown by the researches of Montejo, to the pre-Columbian existence of syphilis in America. They show not only that the disease was known to the Indians, but that the Indians had numerous names for it; that they were fairly familiar with its symptoms and course, and had well-worked-out methods of treatment for it; and that the disease was much milder in its course among the Indians than among the Spaniards, who contracted it from them.

This brief summary of the discoveries of Montejo y Robledo from his researches among original Spanish authorities, furnishes the final link connecting the origin of syphilis with America, and, it would seem, compels us to conclude that syphilis was introduced into Europe from Haiti by the sailors of Columbus on their return in 1493 from his first voyage to America.

THE LANDAU IODIN SERUM TEST FOR SYPHILIS *

ARTHUR W. STILLIANS, M.D.
Associate Professor of Dermatology, Chicago College of Medicine and Surgery; Attending Dermatologist, Cook County Hospital; Consulting Dermatologist, Chicago Lying-In Hospital
CHICAGO

A good deal of interest has been aroused lately in the new serum test for syphilis proposed by Landau.[1] It is declared that this test is more sensitive than the Wassermann reaction and that its simplicity makes it available for every one. Among the many tests said to have these qualities, the Landau demands attention because of the popular interest shown in it and the possibility that it may come into more or less general use. Any new test for deciding so important a diagnosis as that of syphilis must be subjected to the sharpest scrutiny, and tried in many thousand cases.

Landau at first used as a reagent a 0.05 per cent. solution of iodin in liquid petrolatum. The composition of various samples of this solvent varied enough, however, to make it difficult to obtain a reliable reagent, so that he later adopted carbon tetrachlorid (CCl_4) as a solvent. In this he dissolves 1 per cent. of iodin (a saturated solution which requires trituration to complete it), and uses 0.1 c.c. of this reagent to 0.2 c.c. of the serum to be tested. These are shaken together in a test tube 12 mm. in diameter, and allowed to stand at room temperature for four hours. If, at the end of this time, the serum above the decolorized reagent is a clear yellow, the reaction is recorded as positive. If the serum is an opaque grayish-white, it is recorded as negative. Only fresh serum, obtained not more than six hours before, and free from any cloudiness or hemoglobin stain, can be used. If the result is not easy to determine, 0.2 c.c. of ammonia solution may be added to clear up the doubt.

Landau, with his first technic, reported that he obtained, in a series of 122 cases, only one result that did not agree with the clinical diagnosis. This was a positive test in a case of a leg ulcer, clinically and serologically nonsyphilitic. He reported also that the reaction gave fifty-five positive readings in a series of ninety syphilitics, in whom only forty-nine positive Wassermann reactions were obtained.

These results have not been substantiated by others. Golay,[2] using the carbon tetrachlorid reagent, obtained forty-one positive, eleven doubtful, and eleven negative reactions in a series of sixty-three syphilitics, in which only thirty-seven positive Wassermann reactions were obtained. But he also reports in seventeen nonsyphilitics, all of whom had negative Wassermann reactions, a positive Landau test in eight cases. One of these was a case of gonorrhea, three cases of soft ulcer, two of tuberculosis and two of malignant tumor: 47 per cent. positive in nonsyphilitics! He concludes that the test is positive in a large percentage of cases of systemic disease, but reports negative reactions in all of three cases of "skin disease of external origin" and three healthy persons.

Villaret and Pierret[3] report agreement with the Wassermann reaction in thirty-two cases of thirty-nine

---

* From the Dermatological Department of Cook County Hospital.

[2] Golay, J.: La réaction de Landau, Rev. méd. de la Suisse romande, 1914, xxxiv, 571.

[3] Villaret and Pierret, R.: Tr. Soc. biol. de Paris, Presse méd., July 29, 1914, p. 582.

examined, and agreement with the clinical diagnosis in twenty-seven of thirty-three cases.

Capello[4] reports that in forty-one cases, the Landau reaction agreed with the Wassermann in only twenty-seven, leaving fourteen, or 34 per cent., in which it differed. In three cases of late syphilis under mercury treatment, the Wassermann reaction was negative, while the Landau gave a strong positive in two and a doubtful positive in one. In two cases clinically and serologically nonsyphilitic, the Landau test gave a strong positive. Of four cases in which the Wassermann reaction was a strong positive, the Landau gave a doubtful result in one and a frank negative in three.

My technic is the same as that prescribed, except that for the first of my series I used very small test tubes, in order to make the small column of serum longer and more easily seen. Later I adopted the regulation size, 12 mm. diameter, running a series of parallel reactions in both kinds of tubes, until I was satisfied that my results were practically the same with both, and that my early tests could be admitted as reliable. I also used from the beginning twice the prescribed quantities of serum and reagent, 0.4 c.c. of serum and 0.2 c.c. of reagent. But in order to check this with the original technic, and to check my results on each serum, I made each time two tests, one with the original quantities and a parallel test with the double quantities. The measurement of the reagent is a difficult matter in the ordinary pipets. My work was made much easier by the use of a Wright pipet, graduated in 0.1 c.c. In this, several doses of reagent can be taken up, separated by columns of air, and the movement of the thin liquid much more easily controlled.

On shaking the mixture of serum and reagent, an emulsion is formed which soon becomes a light yellow and then white. All serums decolorize the carbon tetrachlorid, so that it separates out and remains as a white layer under the serum.

The reading of the final result is by no means always easy. All degrees of opalescence occur, and even the addition of ammonia does not always clear up the doubt. Golay makes the same observation, and this accounts for the large number of doubtful reactions recorded by him and Capello. I have tried to avoid as far as possible recording doubtful reactions, and I believe that my use of two tests for each serum has been helpful in that direction. Where any doubt existed, I have tried to give the new test the benefit of it.

My results with fifty tests in forty-six cases of syphilis are shown in the accompanying table.

COMPARATIVE RESULTS WITH THE LANDAU AND WASSERMANN REACTIONS

	No. Cases	Landau Reaction			Wassermann Reaction	
		+	+—	—	+	—
Primary syphilis........	5	4		1	5	
Active secondary........	16	7		9	16	
Latent	11	1	1	9	5	6
Tertiary	17	13		4	13	4
Tabes	1			1	1	
Totals	50	25	1	24	40	10

One latent case under treatment gave a positive Landau and a negative Wassermann. This is greatly outweighed by the five latent cases which gave negative Landau reactions and positive Wassermanns. In the tertiary cases the honors are even. Nine cases gave positive reactions with both tests. Four gave positive Landau reactions and negative Wassermanns. Two of these were on the same patient. Four gave negative Landau reactions and positive Wassermanns.

Of forty tests in nonsyphilitics, all of whom had negative Wassermanns, twenty-nine gave negative Landaus, eleven positives. In these eleven cases, no history of syphilis could be obtained, although one, an old hemiplegic, may be suspected because of a history of cerebral hemorrhage at the age of 21. The positive Landau tests in this series were as follows:

One case of ulcer of the cheek from caustic applied by a dentist.
One of five cases of ulcus molle.
Two of five cases of gonorrhea.
One case of gonorrheal epididymitis.
One case of salpingitis and abortion.
One case of pulmonary tuberculosis with lupus of the palate.
One case of hemiplegia with ulcer of the leg.
One case of seborrheic dermatitis.
Two cases of dermatitis venenata, both from rhus toxicodendron.

My results differ from those of the other investigators of this subject in the low percentage of positive results in known syphilitics, 52 per cent. of positives in the forty-six cases, while the Wassermann reaction gave 84.8 per cent. of positives. It might be thought, from the large percentage of positives in tertiary cases, that the administration of iodids had something to do with the production of a positive Landau test. But all our secondary cases received iodids, and the Landau was especially weak in them, differing markedly from all the European writers on the subject, and agreeing most nearly with Kolmer,[5] who reports 71.6 per cent. of positive Landau reactions in Wassermann-positive serums. Mine gave 62.5 per cent. of positive Landaus in Wassermann-positive serums. Kolmer obtained 70 per cent. of positive tests in Wassermann-negative serums, which may be due to the fact that he used only 0.01 c.c. of the reagent, instead of 0.1 c.c., or with the fivefold amounts, 0.05 c.c. of reagent to 1.0 c.c. of serum. If the test depended on the same constituent of the serum that binds complement in the Wassermann test, it might be expected to give with a smaller amount of reagent a larger proportion of positives in syphilitics at the same time that a number of positives in nonsyphilitics would appear. But the corresponding increased percentage of positives in syphilis does not appear in Kolmer's series.

Leaving out the case of old hemiplegia as a suspect syphilis, my series of nonsyphilitics gave 27.8 per cent. of positive reactions. Golay, in seventeen nonsyphilitics, obtained 47 per cent. positive Landau reactions. Capello, in forty-one cases of both classes, obtained a positive Landau reaction in two which are probably nonsyphilitic, one a subacute polyarthritis and the other listed as clinically nonsyphilitic, both giving negative Wassermanns. A test giving so large a percentage of positive results in nonsyphilitic cases can certainly be of no value in the diagnosis of syphilis, and the idea that it is a test for syphilis can do incalculable harm.

The hope with which I undertook this work, that a negative Landau test might prove of value in eliminating syphilis from the diagnostic possibilities of a case, has been destroyed by the failure of the test to equal the Wassermann reaction in my series of known syphilitics. My statistics do not bear out the idea of Golay and Capello, who think that under treatment the test remains positive longer than the Wassermann reaction.

[5] Kolmer, J. A.: Concerning Landau's Color Test for Serodiagnosis of Syphilis, The Journal A. M. A., May 1, 1915, p. 1461.

The Landau reaction is, as Golay says, an interesting phenomenon, which may some day be made use of in research. As a means of diagnosis, however, it deserves no consideration, but should be relegated to the same shelf as its predecessor and possible relative, the iodin reaction of the leukocytic granules.

SUMMARY

1. No reliance can be placed on a positive Landau, for it occurs in a large percentage of nonsyphilitics.
2. A negative Landau is of no value in proving the absence of syphilis, for a large proportion of syphilitics have negative Landaus.
3. So far as this series of cases can show, no definite relation exists between syphilis and the Landau serum reaction.

A FURTHER NOTE ON LANDAU'S COLOR TEST FOR SERODIAGNOSIS OF SYPHILIS *

JOHN A. KOLMER, M.D.
PHILADELPHIA

Shortly after the publication of my paper concerning Landau's color test for the serodiagnosis of syphilis[1] I learned that 0.1 c.c. instead of 0.01 c.c. of the 1 per cent. iodin in carbon tetrachlorid reagent should have been used with 0.2 c.c. of serum. THE JOURNAL,[2] from which I obtained this technic, had quoted from an Italian medical journal[3] which was responsible for the error. Additional foreign literature[4] states that the correct quantity of the iodin reagent is 0.1 c.c. and since my work had been done with 0.01 c.c. reagent or ten times less the amount given by Landau I have continued the work with this correction, the results being summarized in this paper.

A 1 per cent. solution of iodin was prepared according to weight by dissolving 1 gram of iodin crystals in 62.7 c.c. pure carbon tetrachlorid (specific gravity 1.59 at laboratory temperature) and the container was tightly stoppered to prevent evaporation. The regular and routine test was conducted by placing 0.2 c.c. of serum in a small test tube, adding 0.1 c.c. of the reagent and gently shaking until all color had been removed from the reagent.

The reagent has a deep purple blue color and owing to its high specific gravity settles in the test tube below the serum. After thorough agitation the mixture assumes a brownish color and the carbon tetrachlorid quickly settles to the bottom of the tube in a layer resembling chloroform.

Each serum was also tested routinely with five times the quantity of serum and reagent, namely, 1 c.c. of serum and 0.5 c.c. of reagent. This mixture results in the formation of a heavy brownish sediment overlaid with serum.

Immediately after serum and reagent are mixed the whole is distinctly cloudy; after standing for four hours at room temperature a syphilitic serum, according to Landau, becomes clear transparent yellow, whereas with a nonsyphilitic serum the fluid becomes a whitish gray and is opaque.

When 1 c.c. of serum and 0.5 c.c. of reagent are used the readings cannot usually be made at the end of four hours because of insufficient time for clearing. With this technic the mixtures must be centrifuged or the readings delayed for twenty-four hours.

I have experienced considerable difficulty in reading the reactions. With those reactions in which the supernatant serum is perfectly clear or quite cloudy no difficulties arise in recording the result, but in many instances the serum is neither clear nor distinctly cloudy, but is faintly opalescent, so that different observers will vary considerably in reading the same reactions. For this reason a portion of the unused serum should be on hand for comparison; but under any conditions the reading and interpretation of the tests are difficult and unsatisfactory.

I have again tested each serum with Landau's original reagent of iodized petrolatum, prepared by the addition of 5 drops of 10 per cent. tincture of iodin to each 10 c.c. of white paraffin oil, followed by thorough mixing. As the color of this mixture tends to fade spontaneously I have prepared fresh mixtures twice a week. The test with this reagent was conducted by placing 0.2 c.c. serum in a small test tube and adding 2.5 c.c. of the reagent followed by thorough mixing and standing aside at room temperature for from fifteen to twenty-four hours. A control without serum was included with each set of tests.

Immediately after mixing the serum and reagent the mixture is of a light pinkish color; the serum, however, quickly settles to the bottom of the tube and is of a deeper yellow color, while the deep pink tint returns to the supernatant oil. I have usually shaken the tubes once or twice more during the following six hours.

According to Landau a syphilitic serum decolorizes the mixture after fifteen hours, while the color persists a reddish yellow with normal and nonsyphilitic serum.

MATERIALS AND METHOD OF STUDY

In all 172 serums and fourteen cerebrospinal fluids[5] have been tested. The majority of these were collected within twenty-four to forty-eight hours of the time when these tests were made and were centrifuged if necessary to render them clear and free of corpuscles. Markedly opalescent serums as those collected soon after a meal were discarded; the majority were clear while a few were faintly tinged with hemoglobin. The latter were more likely to become cloudy and opaque with the iodin reagent than were perfectly clear serums.

I found no differences, however, in the results of the tests, whether a serum was secured within three hours or three days of the time when the tests were made, and likewise practically the same results were observed with fresh active serums and the same serums after heating at 55 C. (131 F.) for thirty minutes (inactivation). The plan of study was the following:

TECHNIC

(a) Two-tenths c.c. fresh active serum + 0.1 c.c. iodin tetrachlorid of carbon reagent; the results were

[5] I am indebted to Miss A. McNitt of the laboratory of the Philadelphia General Hospital for a number of these serums.

read after standing four hours and again after twenty-four hours at room temperature.

(b) The same technic was repeated after the serum had been heated at 55 C. for half an hour (inactivation).

(c) One c.c. fresh active serum + 0.5 c.c. iodin reagent; the results were usually read after standing twenty-four hours at room temperature.

(d) The same technic was repeated after the serum had been heated at 55 C. for half an hour.

(e) Two-tenths c.c. fresh active serum + 2.5 c.c. iodized petrolatum; the results were read after from fifteen to twenty-four hours at room temperature.

(f) Same technic repeated after the serum had been heated at 55 C. for half an hour.

(g) A Wassermann reaction was conducted with each serum after inactivation, with three different antigens, namely, an alcoholic extract of human heart reenforced with cholesterin; an alcoholic extract of syphilitic liver and an extract of acetone-insoluble lipoids. All serums reacting positively with the three antigens were included and listed as Wassermann positive; those reacting negatively with all extracts were listed as Wassermann negative. In view of the frequent difficulty of establishing a reliable clinical diagnosis of syphilis I have adhered to my former plan of studying the Landau test from the standpoint of Wassermann positive and Wassermann negative serums.

RESULTS

(*a*) *With the Iodized Petrolatum Reagents.*—As stated in my previous paper, the addition of serum to this reagent in the proportions named results in the partial decolorization of the reagent after from fifteen to twenty-four hours in the majority of tests, regardless of whether the serum was from a syphilitic or nonsyphilitic person. Of 92 serums (52 Wassermann positive and 40 Wassermann negative) tested with this reagent, partial loss of color occurred in 75, or 81 per cent., with no distinction between Wassermann positive and negative serums; in 11 serums, or 12 per cent., there was complete or almost complete decolorization, and in 6, or 6 per cent., no change of color.

Cerebrospinal fluids, on the other hand, produced slight or no change in the color of the mixture, regardless of whether they were Wassermann positive or negative.

(*b*) *With Iodin Tetrachlorid of Carbon Reagent.*—The results observed with this reagent are summarized as follows:

1. Of 64 serums yielding *positive Wassermann reactions* and tested in a fresh active condition in amounts of 0.2 c.c. serum with 0.1 c.c. of reagent, 48, or 75 per cent., reacted positively as read at the end of four hours; at the end of twenty-four hours four serums became cloudy and thereby reduced the percentage of positive iodin reactions to about 69 per cent. These results tallied quite closely with those previously reported when 0.01 c.c. of the reagent had been used.

2. Of 84 serums reacting *negatively in the Wassermann reaction* and tested in a fresh active condition in amounts of 0.2 c.c. of serum with 0.1 c.c. of reagent, but 36, or 42.7 per cent., reacted negatively as read at the end of four hours. In my previous work, including 61 W [illegible] serums tested with 0.01 c.c. reagen [illegible] reacted negatively, so that with the larger amounts of reagent the percentage of false positive iodin reactions has been reduced about 13 per cent.

3. The important objection I raised, however, against the iodin test as a practical diagnostic procedure in that it yields a high percentage of falsely positive reactions, is confirmed in this second series of cases.

4. With 1 c.c. of serum and 0.5 c.c. of reagent the results as read at the end of twenty-four hours tallied quite closely with those observed when 0.2 c.c. of serum and 0.1 c.c. of reagent were used. With the larger amounts the reactions usually cannot be read at the end of four hours.

I have worked with other combinations of positive and negative serums and reagents and found 0.4 c.c. of serum with 0.2 c.c. of reagent quite satisfactory in that the quantities are larger and accordingly more easily read than those given by Landau, and the readings may be made after four hours, but the results were almost identical with those observed with the smaller amounts and I have not yet found a combination of serum and reagent that would yield more satisfactory results in the diagnosis of syphilis.

5. While Landau states that only fresh active serums should be used, I have tested serums at different times varying from a few hours to three days after bleeding and found practically no differences in the results. Likewise all serums were tested after heating at 55 C. for half an hour and the results were similar to those observed with active serum. With 82 per cent. of serums the results were identical, while 18 per cent. of serums reacting positively in an active condition were negative when tested after the process of heating or inactivation.

6. With cerebrospinal fluids the results were entirely unsatisfactory, as previously reported. Practically all fluids reacted alike, that is, the color persisted in the reagent collected in the bottoms of the test tubes and the supernatant fluids remained clear irrespective of whether they were Wassermann positive or negative. Of fourteen fluids tested, eight gave strongly positive Wassermann reactions and five reacted negatively, but as stated, all reacted in a similar manner when tested with iodin in carbon tetrachlorid and iodin in paraffin oil reagents.

7. The starch test for unbound iodin was applied by adding 0.5 c.c. of a 1 per cent. solution in distilled water. After a few minutes a blue color at the line of contact between serum and reagent is seen in the majority of tests, while in a few the reaction is quite marked or entirely absent. This test was applied to most serums after the four-hour interval and to the balance after the twenty-four-hour interval, at room temperature.

As an aid in differentiating positive from negative iodin reactions this starch test had failed to be of any value. Of 67 serums remaining clear or giving positive Landau reaction at the end of four hours, 48, or 71 per cent., gave a positive starch reaction, while of 33 serums giving a negative Landau reaction, 31, or 94 per cent., gave a positive starch reaction.

When 0.01 c.c. of iodin reagent is used with 0.2 c.c. serum as in my previous work the starch test is negative in the majority of instances, as in the series of 58 tests so conducted a faint starch reaction was apparent in but six, and four of these occurred in clear serums or positive reactions, according to Landau.

SUMMARY

To sum up, the iodin color test as conducted with the correct technic was found to have no practical value in the serodiagnosis of syphilis because of its irregular results as shown by the low percentage of correct positive reactions with Wassermann positive serums, and more especially by reason of the high percentage of false positive reactions with Wassermann negative serums.

THE ETIOLOGY AND EXPERIMENTAL PRODUCTION OF HERPES ZOSTER

PRELIMINARY NOTE *

EDWARD C. ROSENOW, M.D.
AND
SVERRE OFTEDAL, M.D.
CHICAGO

Head and Campbell[1] have shown that the peripheral manifestations in herpes zoster are due to lesions in the corresponding posterior root ganglia. The character of the lesions in the ganglia described by them and others and the symptoms suggest strongly a microbic origin of this disease. And recently Sunde[2] has demonstrated gram-staining diplococci in a hemorrhagic gasserian ganglion in a case of ophthalmic herpes in an old man who died of a bronchopneumonia three and one-half days after the appearance of the herpes. The evidence, therefore, that bacteria are the cause of the lesions in the ganglia is rather direct, but so far herpes has not been produced experimentally in animals by intravenous injection.

Rosenow[3] has demonstrated that streptococci from the appendixes in appendicitis, from the walls of the gallbladder and the center of gallstones in cholecystitis, from the depths of ulcers of the stomach and duodenum, from the articular exudate in rheumatic arthritis, and the organisms from the subcutaneous nodes in erythema nodosum tend to localize electively in the tissues from which they are isolated. He has also shown that the probable infection atria (tonsils, pyorrheal pockets, suppurating sinuses, etc.) in these diseases harbor streptococci and other organisms showing similar elective localization when injected intravenously into rabbits.

It occurred to us that the presumable infection atrium in cases of herpes zoster might contain streptococci or other bacteria having elective affinity for the posterior root ganglia, and experiments were made accordingly.

Herpes of the skin, tongue or lips and lesions in the corresponding ganglia have been produced in a large number of rabbits and other animals (forty-six) by intravenous injection of the bacteria in emulsions of extirpated tonsils, of mixed cultures and pure cultures of streptococci obtained from tonsils or pyorrheal pockets, and of streptococci in pure culture from the spinal fluid. A number of animals, usually those showing marked herpes of the skin, showed also herpetiform lesions of the viscera, and in these the ganglia of the vagus or sympathetic nerves were found to be hemorrhagic. The tendency of these organisms to localize electively in the ganglia is illustrated by the fact that herpes developed in six guinea-pigs following intraperitoneal injection. The streptococci isolated from the tonsils and other places after recovery, those cultivated on artificial mediums for a time, and those passed through a series of animals no longer show this peculiar property. Broth culture filtrates, proved not to contain streptococci, failed to produce the lesions.

The lesions of the ganglia consist chiefly of hemorrhages and round-cell infiltration, usually most marked just beneath and outside the capsule and surrounding areolar tissue and along the sheath of the corresponding nerve. The blood vessels commonly show marked congestion, and at times are completely or partially filled with mononuclear and polynuclear leukocytes. Gram-staining diplococci and short chains have been found to occur quite constantly in the areas showing lesions in and about the ganglia, but not in the normal portions. Cocci have been found in these lesions, by cultures and sections, when absent in the blood and other tissues. The peripheral lesions in the experimental disease in the animals which recovered, just as in man, have not contained the organisms. Most of the eleven cases studied were typical thoracic herpes zoster, three were cases of recurring herpes, one a marked herpes of the lips and left side of the cheek during pneumonia, and one a mild herpes during an attack of an ordinary cold.

The following experiments will serve to illustrate the results obtained:

Experiment 1.—D. 220, a small white and black dog, was injected intravenously, February 20, with the growth from 45 c.c. of ascites-dextrose-tissue broth of a pure culture of a rather long-chained green-producing streptococcus from the tonsils removed on the second day after the onset of a typical attack of herpes zoster.

February 21: Seems ill and keeps rubbing the left side of head with front paw.

February 22: Seems better, but still rubs gently and slowly left side of head.

February 23: Seems about the same as yesterday. Chloroformed and examined at once. The under surface of the skin of left side of forehead shows a number of hemorrhagic vesicles from which exudes a large amount of serosanguineous fluid when cut across. A few similar lesions are found in the subcutaneous fat over lumbar region on the right side corresponding to the last dorsal vertebra. Under the vesicle on left side of head the periosteum is hemorrhagic over an area 0.5 by 1 cm. The left gasserian ganglion shows a small hemorrhagic area. The spinal cord was not removed. The spinal fluid is turbid and contains a moderate number of large and small mononuclear cells. No other gross lesions.

February 24: *Cultures in ascites-dextrose broth from spinal fluid and hemorrhagic ganglion give pure cultures of short-chained streptococcus, while those from the blood and joint are sterile.*

Experiment 2.—D. 242, a small white dog, was injected intravenously, March 4, with the growth from 40 c.c. of ascites-dextrose-tissue broth of the primary, pure culture of the spinal fluid in a case of typical herpes zoster.

March 6: Seems well. Chloroformed. Marked herpes of inner angle of right eye and of the upper lip. Rather large amount of turbid spinal fluid. Marked hemorrhage of right gasserian ganglion; the left appears normal. No other lesions.

March 8: Cultures from spinal fluid and hemorrhagic ganglion show moderate number of grayish-green colonies of streptococcus only on blood agar plates. The blood, joint fluid and opposite ganglion are sterile.

CHOLESTERINEMIA AND THE WASSERMANN REACTION *

EDWIN HENES, JR., A.B., M.D.
Assistant Admitting Physician, German Hospital; Assistant Visiting Physician, German Hospital Dispensary
NEW YORK

Cholesterin has most important biologic applications: cholesterin and the lipoids are seriously involved in the specific blood tests, and it has been said that "no earnest discussion of serologic work can be undertaken today without reference to them." [1] It is probable that no earnest serologic work today can be properly explained or correctly interpreted without due regard to the cholesterin and lipoid content of the blood. It is the question of the correct interpretation of the Wassermann reaction which first interested me in this work.

Recent work on the Wassermann reaction has tended, first, toward the standardization of this very important clinical test: second, toward the increase in its delicacy, and third, toward the production of a suitable antigen. A review of the literature of the past year or more will show, at a glance, that it is cholesterin with which most, if not all investigators are working. Some of the more recent subjects are entitled as follows:

1. "Cholesterine Reaction in Serodiagnosis of Lues." [2]
2. "Use of Cholesterinized Antigens in The Wassermann Reaction." [3]
3. "Cholesterinized Antigens." [4]
4. "The Use of Cholesterine Antigen in the Wassermann Reaction." [5]
5. "A Method Developed for Obtaining a Standard Wassermann Antigen." [6]
6. "Serum Cholesterol and The Wassermann Reaction." [7]
7. "A Comparison of Cholesterinized and Non-Cholesterinized Artificial Antigens in The Wassermann Reaction." [8]
8. "Modified Technique For Wassermann Reaction." [9]
9. "Antigens in Wassermann Reaction." [10]
10. "Cholesterine-Heart Antigen Proposed by Walker and Swift." [11]

Other papers have undoubtedly been written on the subject, but the ten mentioned clearly show that cholesterin is receiving considerable attention in our newer researches on the Wassermann reaction. A great number of serologists, however, especially as concerns the Wassermann reaction, have failed to take into consideration those apparently uninteresting and unimportant clinical manifestations which, in the great majority of instances, accompany cases of syphilis. We practically never see a case of syphilis which does not at the same time manifest some other clinical abnormality not always dependent on syphilis. I refer to such clinical abnormalities as fever, nephritis, arteriosclerosis, jaundice, etc.

I am not in a position to discuss the various methods which we now see employed in doing the Wassermann test; but if we are to go ahead studying the influence which cholesterin plays in the Wassermann reaction (and by the Wassermann reaction I mean the biologic reaction of that name), must we not take into consideration the pathologic variations in the cholesterin content of the blood? Up to the present time considerable work has been done to determine in which pathologic conditions the cholesterin content of the blood varies,[12] and we have sufficient data safely to say when we can expect either a hypercholesterinemia or a hypocholesterinemia.[13] That all this newer work on the Wassermann reaction should have gone on without considering the cholesterin content of the blood in individual cases is surprising.

We have arbitrarily designated the intensity of the Wassermann reaction numerically: 1 +, 2 +, 3 + and 4 +, depending on the degree of hemolytic inhibition. Why should one case of syphilis show a 1 + reaction and another case a 4 + reaction? Duration of the disease and severity of infection, or effect of treatment, do not always explain the differences in the intensity of the reaction. Is a man with a 1 + reaction less syphilitic than one with a 4 + reaction? Are such experiences as the following unheard of?

1. A case infected thirty years ago with a 4 + and never treated.
2. A case infected twenty years ago with intermittent treatment during this period, with a 4 +.
3. A case of one year's duration, with moderately severe treatment with a 4 +.
4. A case of 4 + vigorously treated, and after two years the reaction is still 4 +.
5. A case in which the reaction increases in spite of proper treatment.
6. A case in which the reaction decreases without treatment.

What do these discrepancies mean? Do they mean anything? Is there something in the blood, something whose quantity varies, responsible? Is it unreasonable to assume that a case is or is not syphilitic, and that the intensity of the Wassermann reaction is determined not by how much syphilis is in the individual's system but by how much cholesterin, or lipoids, which are seriously involved in the reaction, are in that individual's blood serum? The reverse argument that *syphilis affects the lipoid and cholesterin content of the blood does not hold.* I have examined a sufficient number of serums to convince me of that fact. There is no definite relation between cholesterinemia and the present-day numerically interpreted intensity of the Wassermann reaction.

We have been led to believe that cholesterin materially influences the Wassermann reactions. But there seems to be a difference of opinion as to the value of using an antigen to which cholesterin has been added. Some of the conclusions of investigators in this field are as follows:

1. C. C. W. JUDD:
    (*a*) "Cholesterinized antigens do not yield an appreciable number of nonspecific reactions."

---

3. Loyd Thompson:

(*a*) "If the reagents are titrated properly, nonsyphilitics will not give positive results."

(*b*) "Cholesterinized antigen is slightly more delicate than other antigens, and is especially valuable in determining when a cure has been effected, as a positive with it persists after treatment for a longer time than with other antigens."

4. Cyrus W. Field:

(*a*) "Cholesterin seems to increase the velocity of the reaction."

5. I. Chandler Walker:

(*a*) "Cholesterinized alcoholic extracts of human heart have a specific fixation property with syphilitic serums, and they do not give nonspecific fixation with nonsyphilitic serums, provided the reagents are properly titrated."

(*b*) "The serum of syphilitic patients contains a 'something' for which cholesterin has a definite fixation power in the presence of complement."

6. Paul G. Weston:

(*a*) "The cholesterol content of the serums examined bore no constant relation either to the Wassermann reaction or the gross appearance of the serum."

I am not in a position to criticize these conclusions, except to say that I have had serums with astoundingly high measures of cholesterinemia in which the Wassermann reaction was negative; again, inasmuch as P. G. Weston confined his examinations to the bloods of normal individuals and those of paretics, I am inclined to doubt the justification for his conclusion.

It is apparent, nevertheless, from the review just made, that cholesterin can, and seemingly does, influence the Wassermann reaction. May I therefore ask the following questions?

1. Has the Wassermann reaction in a pregnant woman ever changed from 2 + to 4 + during the course of the pregnancy despite treatment?
2. Has the 4 + reaction of a chronic nephritic ever changed to 2 + when that patient became uremic and died even without antisyphilitic treatment?
3. Is the Wassermann reaction influenced at all by fever?
4. Why does an icteric serum frequently inhibit hemolysis?
5. Has the intensity of the reaction ever increased in a convalescent case of typhoid fever?
6. Do not old syphilitics, old with endarteritis and arteriosclerosis, resist treatment, that is, do they not persist with their strong reaction?

I cannot answer these questions; perhaps serologists can. But if we may assume for a moment that the cholesterinemia is responsible for the intensity of the reaction in individual cases, these questions can not only be answered, but I think, can be correctly answered. For in each of the hypothetical cases mentioned, changes in the cholesterin content of the blood could explain these different Wassermann results. Why should the cholesterin content of the blood be absolutely disregarded in interpreting the Wassermann reaction?

Among the many hundreds of cases in which I have made quantitative cholesterin determinations, obtaining the material almost exclusively from the medical and surgical services, and the dispensary patients of the German Hospital, I have about 225 in which the Wassermann reaction was also done.[14] Dr. A. L. Garbat, the attending serologist at the German Hospital, is responsible for the Wassermann results, having used the Citron-Wassermann method, noncholesterinized alcoholic extract of guinea-pig's heart, as an antigen.[15]

On most of the ambulatory cases of the dispensary, it was impossible to obtain full clinical data; but on all of the hospital cases, those data are complete, and especially those that are of importance as influencing the cholesterin content of the blood.

Tabulated briefly, they include the following:

Forty-six cases with 4 + reactions: cholesterin content of blood varying between 0.0007 and 0.00463 grams per cubic centimeter serum, with an average of 0.00234 grams.

Three cases with 3 to 4 + reaction; cholesterin, 0.00117 to 0.00160, average 0.00133.

Twenty-nine cases with 3 + reaction: cholesterin, 0.0007 to 0.00907, average 0.00202.

Thirty-one cases with 2 + reaction: cholesterin, 0.00074 to 0.00463, average 0.00238.

Nineteen cases with 1 + reaction: cholesterin, 0.0004 to 0.00399, average 0.00202.

Eighteen cases with ± reaction: cholesterin, 0.00097 to 0.00262, average 0.00174.

Seventy-nine cases with negative reaction: cholesterin, 0.000501 to 0.00621, average 0.00225.

It will be noted that of these 225 cases, seventy-nine had negative and 146 positive Wassermann reactions. The cholesterinemia in the negative cases averages 0.00225, and in the positive, 0.00196. Looked at collectively, these figures probably do not mean very much; but when one looks at individual cases, the figures are far more interesting.

In Table 1 are presented a few cases with positive Wassermann reactions, their cholesterinemia, and the coincident clinical conditions, which in my opinion explain the cholesterinemias regardless of the luetic infection.

TABLE 1.—CASES WITH POSITIVE WASSERMANN REACTIONS, THEIR CHOLESTERINEMIA, AND CLINICAL CONDITIONS

Case No.	Wassermann	Cholesterinemia gm. per c.c. serum	Coincident Clinical Condition
1	4 +	.00247*	Obliterating endarteritis
2	4 +	.00381	Incomplete abortion
3	4 +	.00374	Chronic nephritis
4	4 +	.00251	Angina pectoris
5	3 +	.00265	Incomplete abortion
6	1 +	.00378	Pregnancy
7	1 +	.00385	Chronic nephritis

* It is to be remembered that the average *normal* cholesterinemia is about 1.5 gm. per cubic centimeter of serum.

Coming, as this paper does, with a questioning finger pointed at the Wassermann reaction as today interpreted and relied on from a therapeutic point of view, the following questions arise:

If cholesterinized antigens influence the Wassermann as we have shown they do, then I ask:

Why is not the 4 + with cholesterinemia of 0.00247 a stronger reaction than the 4 + with cholesterinemia of 0.00381? Does not the difference in the blood cholesterin in these two cases have some effect on the Wassermann reaction? We call them both 4 +.

---

[14] The total includes examinations as late as Feb. 1, 1915.

[15] Citron, J. B.: Immunity, Methods of Diagnosis and Therapy and Their Practical Application, translated by A. L. Garbat, Ed. 2, Philadelphia, P. Blakiston's Son & Co., 1914.

Furthermore, in Table 2 are cited cases with equally strong Wassermann reactions, but with widely varying cholesterinemias. Explaining the cholesterinemia by the coincident clinical conditions which, unfortunately, I was unable to obtain in detail in these particular cases, I present this series (Table 2).

TABLE 2.—CASES WITH EQUALLY STRONG WASSERMANN REACTIONS, BUT WIDELY VARYING CHOLESTERINEMIAS

Case No.	Wassermann	Cholesterinemia
8	4 +	.00147
9	4 +	.00390
10	4 +	.00102
11	4 +	.00463
12	4 +	.00131
13	4 +	.00355

Why is not the 4 + of Case 8 much stronger than the 4 + of Case 9, or that of Case 10 much stronger than that of Case 11? Why, with such decided differences in the cholesterinemia, do we designate all the Wassermann reactions 4 +? Why are not the cholesterinemias of Cases 9, 11 and 13 responsible for the degree of hemolytic inhibition which we designate as 4 + and not the syphilis?

TABLE 3.—CASES OF HIGHER CHOLESTERINEMIA WITH THREE PLUS THAN WITH FOUR PLUS REACTIONS

Case No.	Wassermann	Cholesterinemia
14	4 +	.00360
15	3 +	.00360
16	4 +	.00160
17	3 +	.00233
18	4 +	.00137
19	3 +	.00408

In the series of Table 3, in which the 3 + reactions have a higher cholesterinemia than the 4 + reactions, why are not the reactions of Cases 15, 17 and 19 what they are because of the hypercholesterinemia in these cases? With marked differences in the cholesterinemia, I should think we would have more marked differences in the interpretation of the Wassermann reaction. If such calculation is permissible, a 4 + reaction is 25 per cent. stronger than a 3 +, but the cholesterinemia of Case 19 is 300 per cent. higher than that of Case 18. So why not call the reaction of Case 19 something decidedly lower than 3 +? Why not 1 +?

TABLE 4.—CASES OF HIGHER CHOLESTERINEMIA WITH FOUR PLUS THAN WITH ONE PLUS REACTIONS

Case No.	Wassermann	Cholesterinemia
20	4 +	.00307
21	1 +	.00127
22	4 +	.00390
23	1 +	.00125
24	4 +	.00300
25	1 +	.00100

In the series of Table 4, in which, vice versa, the 4 + reactions have a decidedly higher cholesterinemia than the 1 +, why are not the 1 + reactions with a normal cholesterinemia just as strong as the 4 + with a hypercholesterinemia? Biologically, there is a difference, of course; but are we correct when we make such a big clinical difference in our interpretation? Do we do ourselves justice from a therapeutic and a prognostic point of view? Let us say, for example, that Case 22 with a 4 + reaction has gallstones which account for the very high cholesterin figure of 0.00390. Aware, or not aware of the gallstones, but mindful of the hypercholesterinemia, are we not justified in believing that our 4 + patient is just as nearly cured of his syphilis as is our 1 + patient?

These cases, I think, show that there ought to be at least a reasonable doubt as to our justification in arbitrarily numbering our Wassermann reactions as we do.

Continuing on the assumption that serum cholesterin influences the Wassermann reaction just as a cholesterinized antigen does, the following hypothetical cases are far from unreasonable:

CASE 1.—A married woman with syphilis becomes pregnant and, let us say, aborts at the sixth month. Experience has shown us that during these six months the quantity of serum-cholesterin constantly increases above normal, and at the termination of pregnancy slowly returns to normal. Why, if cholesterin influences the biologic reaction which we call the Wassermann reaction, should we not take the serum-cholesterin into consideration?

CASE 2.—Again, a patient with syphilis contracts typhoid fever, and the usual course of hyperpyrexia is run; during that fever period, the serum-cholesterin is decidedly diminished, and when convalescence sets in, rises considerably above normal, and then slowly comes back to normal. If, as Pighini says, cholesterol may be the chief constituent of the Wassermann reaction, why should not fluctuations in the cholesterinemia be taken into consideration when interpreting this reaction? Bürger and Beumer assert that the outcome of the Wassermann reaction is not dependent on the presence of simply more or less of cholesterol or lecithin in the serum. My experience bears out their assertions. Hypercholesterinemia in itself, in my examinations at least, does not give a positive Wassermann reaction. I have had a few cases with exceedingly high measures of cholesterinemia with a negative reaction.

CASE 3.—A patient with syphilis, with a 2 + positive Wassermann reaction, under treatment, during the course of observation develops a cirrhosis hepatis and becomes markedly jaundiced. The Wassermann test done in this icteric serum shows a reaction stronger than 2 +. Jaundice, no matter from what cause, is accompanied by a decided increase in the serum-cholesterol above the normal. Why, under these circumstances, is not the hypercholesterinemia responsible for the increased intensity in the Wassermann reaction, and why is it not accountable for the frequent fixation of complement by icteric serums? On the other hand, if in such a hypothetical case as outlined, with jaundice present, the Wassermann should stay 2 +, would it not seem reasonable on this basis to consider that our therapy had favorably influenced the syphilis, and notwithstanding the fact that the Wassermann had stayed 2 + (as we read it today), the reaction should be interpreted as something less than 2 +?

CASE 4.—In a case which, by the way, is under treatment by a colleague of mine, there is a 2 + Wassermann. This reaction continues positive despite efficient and prolonged treatment. The man's serum happens to contain 0.00463 gm. of cholesterin per cubic centimeter. I do not know what is producing this hypercholesterinemia; perhaps it is due to arteriosclerosis. But why is not the hypercholesterinemia responsible for the fact that the Wassermann does not go below 2 +? *Is not this man entitled to a lower interpretation?* It might be argued that the syphilis is responsible for the sclerosis and therefore for the hypercholesterinemia. But I have many cases of arteriosclerosis with negative Wassermann reactions and marked hypercholesterinemias.

CASE 5.—Another actual case is that of a young married woman, aged 21. One year ago she had a 4 + Wassermann. Since that time she has been vigorously treated, and yet the reaction stays at 4 +. The cholesterinemia in this case is 0.00287 gm. per cubic centimeter of serum. Is not this hypercholesterinemia keeping the Wassermann at 4 +, and is not this patient entitled to a lower interpretation?

CASE 6.—Another actual case is that of a man aged 39, suffering from chronic nephritis and marked secondary anemia. The Wassermann reaction in this case is ± and the cholesterinemia 0.00183 gm. per cubic centimeter of serum. In the absence of a luetic history, we look with doubt on this Wassermann reaction, but the biologic reaction did show some inhibition of hemolysis. Some time later, this man developed a fever of 102 F., a clinical condition which reduces the measure of cholesterinemia; it was reduced to 0.00108, almost 80 per cent., and the biologic test which we call the Wassermann reaction was negative at the second examination.

In diabetes, nephritis,[16] cholelithiasis,[17] icterus from any cause, obesity and arteriosclerosis, in which profound changes in the cholesterin content of the blood exist, are we to ignore just that blood constituent which today serologists are most interested in relative to the Wassermann reaction? It is just because of this fluctuating cholesterinemia under pathologic conditions — a fluctuation that a rather large experience has taught us is pretty constant — that I present my ideas on the subject of the Wassermann reaction. The subject of cholesterinized antigens has called forth these ideas.

SUMMARY

1. The cholesterin content of the blood varies considerably under various pathologic conditions. Placing the normal cholesterinemia at 0.00150 gm. per cubic centimeter of serum, variations between 0.0004 and 0.0102 gm. per cubic centimeter have been encountered, the latter, as far as I know, the highest figures ever recorded.
2. We are in a position to know when a hypocholesterinemia or a hypercholesterinemia can be expected.
3. The addition of cholesterin to the antigen of the Wassermann reaction increases the rapidity and intensity of hemolytic inhibition.
4. Serologists have failed to take into consideration the pathologic variations of the blood cholesterin in interpreting the Wassermann reaction.
5. Syphilis, in itself, is not primarily responsible for a hypercholesterinemia.
6. Hypercholesterinemia, in itself, does not give a positive Wassermann reaction.

CONCLUSIONS

Conclusions, from a work of this sort, must of necessity be submitted with reservation. While acknowledging my inability to prove nothing more than the facts which I have presented, I nevertheless offer the following theoretical conclusions:

The lipoid content of the blood serum determines the intensity of the biologic reaction employed in the diagnosis of syphilis. Cholesterinemia and lipoidemia have been shown to follow parallel curves.[18] We are justified in assuming then that cholesterin determines the intensity of this reaction. Having been shown that cholesterin in the antigen does intensify the Wassermann reaction, why should the cholesterin of the blood serum be utterly disregarded? Just because the cholesterinemia shows such marked fluctuations under various pathologic conditions, and such marked fluctuations in the course of certain diseases (infectious diseases, nephritis) and certain physiologic processes (pregnancy), the serum cholesterin must be taken into consideration in the interpretation of the Wassermann reaction, whether cholesterinized or noncholesterinized antigens are used.

The nearer the blood cholesterin approaches the normal, in any given case, the stronger is the Wassermann in that case. For example: A 4 + Wassermann with a normal cholesterinemia (not taking conditions of hypocholesterinemia into consideration) should be interpreted, according to our present-day standards, as the strongest reaction. A 4 + reaction with a hypercholesterinemia is a weaker reaction than a 4 + with a normal cholesterinemia. A 4 + reaction with a marked hypercholesterinemia is *no stronger than a 2 +* with a moderate hypercholesterinemia. A 4 + reaction in a chr[illegible] less than a 4 +. It is the [illegible] icteric serum that often interferes with the reading of a Wassermann reaction. Failures or discouragements in our antiluetic therapy, as judged by the Wassermann reaction, may be due to certain hypercholesterinemias in individual cases. Surely there ought to be some difference in the Wassermann reactions of bloods which show respectively a cholesterinemia of 0.0007 and 0.00463 gm. per cubic centimeter of serum; and yet, these two actual extremes gave a 4 + reaction — and we call them the same, and judge them *in the same way.*

Finally, our interpretation of a positive Wassermann reaction would be much more accurate if we, jointly, would take the cholesterinemia into consideration. That does not, of necessity, mean that a quantitative cholesterin determination should form part of the Wassermann reaction; but those clinical factors which we know influence the cholesterinemia should most certainly be recognized and considered.

TAENIA SAGINATA

A CASE PRESENTING STRUCTURAL ABNORMALITIES AND ASSOCIATED WITH SPURIOUS PARASITISM IN AN INFANT

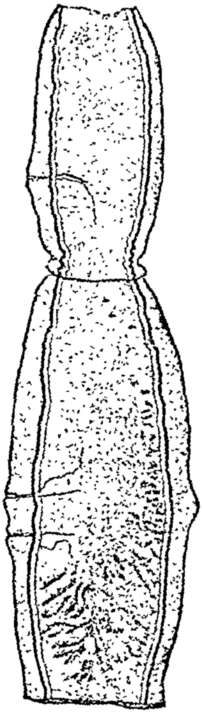
MAURICE C. HALL, PH.D.
Assistant Zoologist, U. S. Bureau of Animal Industry
WASHINGTON, D. C.

Segments of tapeworm sent in to the U. S. Bureau of Animal Industry by Dr. Louis T. Cassidy of Norwich, Conn., were found on examination to be *Taenia saginata.* Among the segments was one presenting a meristic variation consisting in the unilateral duplication of the genital pore and canals in one segment with what is apparently the formation of a rudimentary genital pore alone on the side of the segment opposite the two pores which are provided with canals. The segment is enlarged, being 20 mm. long and 9.5 mm. wide, while an adjoining segment is only 15 mm. long and 7 mm. wide. The uterine branching is somewhat diffuse and irregular, and the eggs present some abnormalities of shape and structure. An examination of a number of eggs did not disclose the presence of any developed hexacanth embryos.

The tapeworm segments were passed by a Polish child said to be from 14 to 18 months old. This seems like a very young age at which to be harboring tapeworms resulting from the eating of underdone beef and, as a matter of fact, such cases are rare. They are perhaps to be attributed to the use of scraped raw beef, the treatment advocated by Weiss in cases of chronic diarrhea, but as children are fed in many households on exactly the same food as the adults, some of these cases may result from the ingestion of very rare steak, roasts, etc.

Accompanying the tapeworm segments from the infant was a beetle larva, said to have been passed at the same time, which I identified as *Tenebroides mauritanicus,* an identification which was confirmed by Mr. A. E. Schwartz of the U. S. National Museum. This beetle is commonly found in cereals, flour, old bread, etc., and is, of course, not parasitic. It is frequently sent in to entomologists, according to Mr. Schwartz, with a history of being passed in the feces. In such cases there are two evident possibilities: That the larva is found in the feces as a result of its occurrence in the vessel used or getting into the feces in some such way after passage; or that the larva is ingested in food, such as breakfast food, old bread, etc., and passes the digestive tract dead but undigested. It is well known that various diptera, alive or dead, may pass through the alimentary tract undigested, and there appears to be no reason why the chitinous structure of a coleopterous larva should not resist digestion equally well. I have collected such larvae from the stomach of rodents, *Sciurus aberti mimus,* but of course these larvae had not been subjected to the digestive action of the entire alimentary tract. There is every likelihood that the resistant undigestible chitinous structure would be unbroken in the case of a larva eaten by a baby. It might also be noted that the presence of such a larva in the feces fits in well with the carelessness in regard to a child's diet suggested by the presence of *Taenia saginata* at so early an age.

The tapeworm most commonly found in children is *Hymenolepis nana. Hymenolepis diminuta* has been found in suckling infants. According to Grimm,[1] *Taenia solium* has been reported by von Pardo[2] in an infant 5 months old. *Taenia saginata* has been reported by Comby[3] from an infant 9 months old, which had been fed raw beef juice. Westhoff[4] reports *Taenia saginata* from an infant 8 months old, and notes that the child had been fed a half pound of minced beefsteak daily. Two cases have been reported in which tapeworms are recorded from children 5 days old. In one case, European, recorded by Mueller,[5] the tapeworm reported as *Taenia solium,* was said to be 1½ feet long. In the other case, reported for the Long Island Hospital, New York, by Armor,[6] gravid segments of *Taenia solium* are said to have been passed after the administration of calomel following trismus on the fourth day. No further evidence of tapeworm was seen during the child's first year. The mother of the child was found to have a tapeworm, *Taenia solium.* Reports of cases of tapeworm in five-day old infants must be regarded as apparently due to error or confusion of some sort.



Taenia saginata, showing duplication of genital pores in a segment.

ARTIFICIAL PNEUMOTHORAX

WITH REPORT OF FIFTEEN CASES

MALCOLM F. LENT, M.D.
Medical Director, Stony Wold Sanatorium
LAKE KUSHAQUA, N. Y.

During the past two years we have attempted the lung compression treatment in thirty selected cases, most of which were far advanced, and in which the disease was steadily progressing. In fifteen of these we were unsuccessful on account of dense pleural adhesions; in fifteen we were more or less successful, according to the degree of lung collapse.

While it would be impossible to make any hard and fast rule in every case, in general the indications and contraindications may be summed up as follows:

INDICATIONS

The ideal case is one in which the disease is limited to the upper portion of one lung, an acute progressive condition, generally with signs of softening, but which has not responded to the usual therapeutic measures.

The treatment is indicated in cases with marked involvement of one lung, with a moderate infiltration of the opposite lung, preferably the apex; râles may or may not be present.

The treatment in cases of severe and uncontrollable hemorrhage has often given brilliant results.

Some cases of pulmonary tuberculosis, complicated by pleurisy with effusion, offer an excellent opportunity of giving pneumothorax treatment. Lung abscesses and bronchiectasis are occasionally benefited.

Complications, such as tuberculous laryngitis, may improve if the patient is doing well otherwise. In one of our cases a deep ulceration of the left ventricular band healed entirely, and the infiltration of the left false cord, which had covered the true cord for months, entirely absorbed and retracted. We had been treating this larynx with intralaryngeal application of liquor formaldehydi, but no marked improvement was noticed until the patient commenced gaining under the collapse treatment.

We would not hesitate to try the lung compression in hopeless cases complicated by tuberculous enteritis. The symptoms referable to the lungs will improve in proportion to the extent of the lung collapse. Tuberculosis of the intestines is, however, a grave complication, whether the treatment is given or not. Some writers assert that the enteric complication may improve or even be cured if the patient is doing well otherwise; our patients who developed tuberculous enteritis after the treatment was begun lost steadily, owing to the progressive intestinal involvement, although the symptoms referable to the lungs improved.

CONTRAINDICATIONS

The chief contraindications are as follows: An extensive or progressive lesion in the opposite lung to the one to be collapsed, or disseminated miliary tuberculosis would preclude the gas treatment. The treat-this Wassermann reaction, but the biologic reaction did show some inhibition of hemolysis. Some time later, this man developed a fever of 102 F., a clinical condition which reduces the measure of cholesterinemia; it was reduced to 0.00108, almost 80 per cent., and the biologic test which we call the Wassermann reaction was negative at the second examination.

In diabetes, nephritis,[16] cholelithiasis,[17] icterus from any cause, obesity and arteriosclerosis, in which profound changes in the cholesterin content of the blood exist, are we to ignore just that blood constituent which today serologists are most interested in relative to the Wassermann reaction? It is just because of this fluctuating cholesterinemia under pathologic conditions — a fluctuation that a rather large experience has taught us is pretty constant — that I present my ideas on the subject of the Wassermann reaction. The subject of cholesterinized antigens has called forth these ideas.

SUMMARY

1. The cholesterin content of the blood varies considerably under various pathologic conditions. Placing the normal cholesterinemia at 0.00150 gm. per cubic centimeter of serum, variations between 0.0004 and 0.0102 gm. per cubic centimeter have been encountered, the latter, as far as I know, the highest figures ever recorded.
2. We are in a position to know when a hypocholesterinemia or a hypercholesterinemia can be expected.
3. The addition of cholesterin to the antigen of the Wassermann reaction increases the rapidity and intensity of hemolytic inhibition.
4. Serologists have failed to take into consideration the pathologic variations of the blood cholesterin in interpreting the Wassermann reaction.
5. Syphilis, in itself, is not primarily responsible for a hypercholesterinemia.
6. Hypercholesterinemia, in itself, does not give a positive Wassermann reaction.

CONCLUSIONS

Conclusions, from a work of this sort, must of necessity be submitted with reservation. While acknowledging my inability to prove nothing more than the facts which I have presented, I nevertheless offer the following theoretical conclusions:

The lipoid content of the blood serum determines the intensity of the biologic reaction employed in the diagnosis of syphilis. Cholesterinemia and lipoidemia have been shown to follow parallel curves.[18] We are justified in assuming then that cholesterin determines the intensity of this reaction. Having been shown that cholesterin in the antigen does intensify the Wassermann reaction, why should the cholesterin of the blood serum be utterly disregarded? Just because the cholesterinemia shows such marked fluctuations under various pathologic conditions, and such marked fluctuations in the course of certain diseases (infectious diseases, nephritis) and certain physiologic processes (pregnancy), the serum cholesterin must be taken into consideration in the interpretation of the Wassermann reaction, whether cholesterinized or noncholesterinized antigens are used.

The nearer the blood cholesterin approaches the normal, in any given case, the stronger is the Wassermann in that case. For example: A 4 + Wassermann with a normal cholesterinemia (not taking conditions of hypocholesterinemia into consideration) should be interpreted, according to our present-day standards, as the strongest reaction. A 4 + reaction with a hypercholesterinemia is a weaker reaction than a 4 + with a normal cholesterinemia. A 4 + reaction with a marked hypercholesterinemia is no stronger than a 2 + with a *moderate hypercholesterinemia.* A 4 + reaction in a chronic nephritic is something less than a 4 +. It is the hypercholesterinemia of an icteric serum that often interferes with the reading of a Wassermann reaction. Failures or [illegible] in our antiluetic therapy, as judged by [illegible] reaction, may be due to certain hypercholesterinemias in individual cases. Surely there ought to be some difference in the Wassermann reactions of bloods which show respectively a cholesterinemia of 0.0007 and 0.00463 gm. per cubic centimeter of serum; and yet, these two actual extremes gave a 4 + reaction — and we call them the same, and judge them in the same way.

Finally, our interpretation of a positive Wassermann reaction would be much more accurate if we, jointly, would take the *cholesterinemia into consideration.* That does not, of necessity, mean that a quantitative cholesterin determination should form part of the Wassermann reaction; but those clinical factors which we *know influence the cholesterinemia should most* certainly be recognized and considered.

ARTIFICIAL PNEUMOTHORAX

WITH REPORT OF FIFTEEN CASES

MALCOLM F. LENT, M.D.
Medical Director, Stony Wold Sanatorium
LAKE KUSHAQUA, N. Y.

During the past two years we have attempted the lung compression treatment in thirty selected cases, most of which were far advanced, and in which the disease was steadily progressing. In fifteen of these we were unsuccessful on account of dense pleural adhesions; in fifteen we were more or less successful, according to the degree of lung collapse.

While it would be impossible to make any hard and fast rule in every case, in general the indications and contraindications may be summed up as follows:

INDICATIONS

The ideal case is one in which the disease is limited to the upper portion of one lung, an acute progressive condition, generally with signs of softening, but which has not responded to the usual therapeutic measures.

The treatment is indicated in cases with marked involvement of one lung, with a moderate infiltration of the opposite lung, preferably the apex; râles may or may not be present.

The treatment in cases of severe and uncontrollable hemorrhage has often given brilliant results.

Some cases of pulmonary tuberculosis, complicated by pleurisy with effusion, offer an excellent opportunity of giving pneumothorax treatment. Lung abscesses and bronchiectasis are occasionally benefited.

Complications, such as tuberculous laryngitis, may improve if the patient is doing well otherwise. In one of our cases a deep ulceration of the left ventricular band healed entirely, and the infiltration of the left false cord, which had covered the true cord for months, entirely absorbed and retracted. We had been treating this larynx with intralaryngeal application of liquor formaldehydi, but no marked improvement was noticed until the patient commenced gaining under the collapse treatment.

We would not hesitate to try the lung compression in hopeless cases complicated by tuberculous enteritis. The symptoms referable to the lungs will improve in proportion to the extent of the lung collapse. Tuberculosis of the intestines is, however, a grave complication, whether the treatment is given or not. Some writers assert that the enteric complication may improve or even be cured if the patient is doing well otherwise; our patients who developed tuberculous enteritis after the treatment was begun lost steadily, owing to the progressive intestinal involvement, although the symptoms referable to the lungs improved.

CONTRAINDICATIONS

The chief contraindications are as follows: An extensive or progressive lesion in the opposite lung to the one to be collapsed, or disseminated miliary tuberculosis would preclude the gas treatment. The treatment would not be justifiable in patients even though far advanced who are doing well under the usual therapeutic measures. Generally, basal lesions in the opposite lung are contraindications and are less favorable in the collapsed lung. Endocarditis and nephritis would lessen the chances of recovery in proportion to their severity. While dense pleural adhesions could not, strictly speaking, be considered contraindications, they are nevertheless the chief cause of a large percentage of failures.

TECHNIC

The Floyd-Robinson apparatus is the one used by us. It is very simple and easy to operate. It being determined to collapse a lung in a selected case, the patient is given beforehand one-eighth grain of morphin hypodermically for the first, rarely, for the subsequent injections.

Factors Which Should Be a Guide in Selecting the Point of Puncture.—An area is chosen as far away as possible from the original site of the disease, as here there are less likely to be found pleural adhesions. The physical signs are very often misleading. We endeavor to find an area where there is good lung resonance, good breathing, no adventitious sounds, preferably in the seventh or eighth interspace, scapular line, or at any point between the anterior axillary line and the scapular line. Efforts to find a free pleural space are often a failure, and frequent attempts have to be made in different places before a free space is found. We have often failed where by percussion and auscultation we had reason to believe we would be successful, and vice versa.

Position of the Patient.—This will necessarily vary according to the point of election. The patient lies on the side, with the lung to be collapsed uppermost. A pillow is placed in the axilla of the side on which the patient is reclining. This facilitates the widening of the intercostal space.

Preparation of the Skin.—After being properly sterilized, a small area of the skin is painted with tincture of iodin and the excess removed with alcohol.

Cocainization.—An all glass syringe is used, with a platinum needle just long enough (1 inch) to pass through the parietal pleura. We have found that 2 c.c. of a 0.25 per cent. novocain solution gives excellent results. The index and middle fingers of the left hand are placed on the upper border of the rib. A large sized wheal is made in the skin between the ribs. The tissues are then carefully cocainized, waiting until the structures in advance of the needle are thoroughly cocainized before advancing the needle farther. When the parietal layer of pleura is reached, the patient often feels a slight pricking sensation, and here we use the novocain solution freely. The structures from without inward offering resistance to the needle are as follows: the skin; external intercostal fascia, very dense; middle intercostal fascia, very little resistance; internal intercostal fascia and pleura, quite dense and generally perceptible resistance; when the pleura is thickened, marked resistance. A small puncture is now made through the epidermis and the dense external intercostal fascia with a cataract knife, and we are now ready to introduce the gas needle. The needle is held in the hollow of the right hand, between the thumb and index finger, and the tip of the index finger is pressed against the chest wall in order to have the needle under perfect control. With the gas needle we can readily determine the different layers of tissue through which it is passing, and it often passes through them with an audible snap.

The needle having pierced the external and middle intercostal fascia, we are now obliged to proceed cautiously as we approach the internal intercostal fascia and the costal pleura. The rubber tubing, having been previously connected with the needle, we now pull out the obturator and refer frequently to the manometer reading. When the needle rests against the costal pleura, a very slight oscillation can be seen, but by advancing the needle very slightly, if there are no pleural adhesions, a good free space may be observed, giving a reading, say from — 4 to — 10 cm., or — 6 to — 12 cm., actual reading. The negative reading is naturally greater during inspiration than expiration. If there are slight pleural adhesions, the reading may not be more than from — 2 to — 4 cm.

A suitable space having been found, we now close the cock leading to the manometer and slowly introduce 50 c.c. of nitrogen gas, the gas being warmed by placing the middle coils of rubber tubing in a basin of hot water; then shutting off the gas, we again consult the manometer carefully, and so on until the gas needed for the individual case is given. In new cases it is far better to inject a small amount of nitrogen gas, say from 300 to 500 c.c., leaving a negative end reading, then give refills every three to five days until gradually a total collapse of the lung is obtained. This overcomes the danger and discomfort caused by displacing the heart and other organs too rapidly, and by allowing the heart time to accommodate itself to its new position. A large needle is used for the initial injection, a smaller one for the refills.

DANGERS AND SEQUELAE

The following are some of the complications that might follow the induction of artificial pneumothorax: Pleurisy with effusion may occur in as high as 50 per cent. of the cases. The cause of this is not clear; some writers believe that it is due principally to chilling of the body, others to faulty technic, and still others to the mechanical irritation of the layers of the pleura, due to the foreign body, nitrogen gas. The fluid in a large percentage of the cases is found to contain tubercle bacilli. This complication, though rarely serious, is an annoying one. The fluid persists for a long time, but generally should not be removed unless causing disturbing symptoms; the fluid may then be withdrawn and nitrogen gas introduced to take its place. Tuberculous pyopneumothorax occurs in a small percentage of these effusions, but does not necessarily give a bad prognosis under the expectant treatment. Some instances of secondary infections have been reported, in which cases the outlook, unfortunately, must be regarded as very serious.

Shock: While numerous cases of shock have been reported in literature, and the real cause is still in doubt, this can probably be avoided by careful cocainization of the tissues and by the initial injection of morphin.

Gas Embolism: If the manometer is carefully consulted, and a good free oscillation is observed before any gas is introduced, this danger may be considered remote.

Emphysema: Emphysema, superficial or deep, may be encountered, but rarely produces any serious symptoms. The subcutaneous variety is due either to too great intrapleural pressure, or to the patient coughing during or soon after the operation, thereby forcing the nitrogen gas out of the pleural space, which becomes diffused along the subcutaneous tissue. The deep variety is undoubtedly due to excessive intrapleural pressure. Both varieties of emphysema generally pass off in from twelve hours to two or three days.

Puncture of the Lung: The puncture of the lung parenchyma, followed by slight bleeding, may occur, but generally does not cause any serious symptoms; spontaneous pneumothorax might ensue where no adhesions prevent.

Dilatation of the Heart: This is a serious complication, and is generally due to too great intrathoracic pressure. It is far better to be satisfied with allowing the end reading to remain at zero, rarely above + 4, and gradually to induce a pneumothorax and permit the heart to accommodate itself to the increased pleural pressure.

Pain more or less severe caused by breaking up of pleural adhesions may be mentioned among the complications. Generally in left-sided gas cases the apex of the heart is displaced to the right to a greater or less degree.

REPORT OF CASES

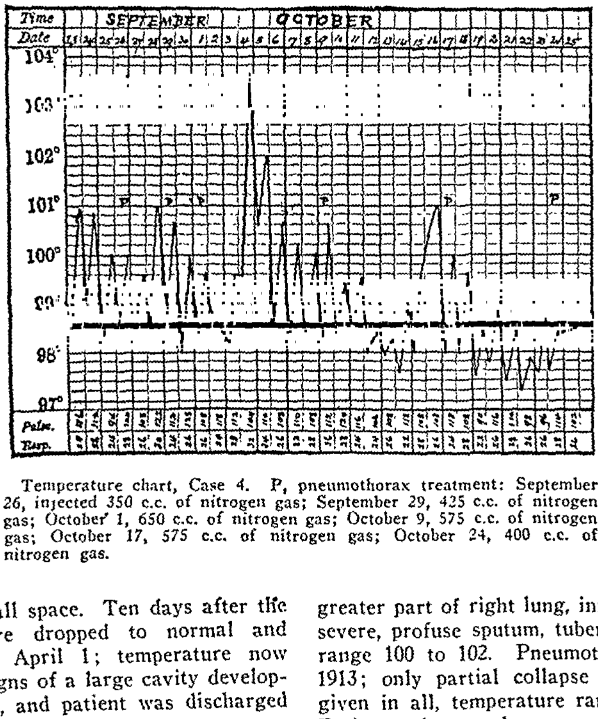
The following is a report of fifteen cases in which we were more or less successful, according to the degree of lung collapse.

Case 1 (1198).—M. P., aged 24. Admitted Nov. 2, 1912, with marked consolidation and considerable moisture upper half left lung, slight infiltration right apex. Severe cough and profuse expectoration. Beginning Feb. 10, 1913, temperature range 101 to 102. Pneumothorax begun February 15, manometer reading —2, —5 cm., injected 325 c.c. of gas, end reading + 2, —2. Refills were given at varying intervals until March 15, when treatment was discontinued on account of the resulting small space. Ten days after the first injection the temperature dropped to normal and remained practically so until April 1; temperature now ranged from 101 to 103, with signs of a large cavity developing at the top of the left lung, and patient was discharged May 10, 1913, unimproved.

Case 2 (1324).—H. S., aged 20. Admitted Sept. 22, 1913, with marked consolidation upper half left lung, slight infiltration right apex; severe cough, profuse expectoration with bacilli present; temperature range 100 to 101.5. Gas treatment begun Oct. 17, 1913. Puncture was made in the ninth intercostal space, scapular line, manometer reading 3, —8. Injected 350 c.c. of nitrogen gas, end reading —1.5, —4. Nineteen refills were given in all, at intervals of a few days to one to two weeks, quantity of gas injected ranging from 300 to 600 c.c., and, from the physical findings, a good collapse was obtained. Four days after the treatment was begun the temperature dropped from the range of 100 to 101.5 to 99 to 100, cough improved, sputum lessened. One month after the initial injection, tuberculous enteritis developed, and while the symptoms referable to the lungs all improved, the patient lost flesh steadily and was discharged May 2 unimproved, probably because of the enteric complication.

Case 3 (1335).—M. M., aged 18. Admitted Oct. 25, 1913, with foci through the greater part of the left lung, infiltration right apex. Moderate cough and sputum, tubercle bacilli present. February 1, temperature 100.5 in the afternoon; March 9, pneumothorax treatment given. Temperature dropped to normal after four days and remained so until date of discharge, April 13, 1914. The gas was administered six times, and a good collapse of the lung was obtained. Cough and expectoration lessened, but patient developed tuberculous enteritis and was discharged unimproved.

Case 4 (1311).—I. B., aged 25. Admitted Aug. 16, 1912, with involvement throughout the greater part of the right lung, cavity at top, left lung clear; troublesome cough, profuse expectoration, tubercle bacilli present, temperature ranging from 100 to 101, in the afternoon, pulse and respiration in proportion. Pneumothorax was given Sept. 26, 1913, manometer reading —8, —13, injected 350 c.c. of nitrogen gas, end reading —3, —7. Temperature gradually returned to normal by October 20 and has remained so ever since. Thirty-three refills have been given in all. Patient has only a few spots of mucoid sputum two or three times a month, tubercle bacilli absent since March, 1914; gain in weight 23¼ pounds. This is a case in which an acute, progressive disease was arrested by compression of the lung. Patient is now doing work in the sanatorium and is clinically well. The temperature chart showing the result of the treatment is reproduced herewith.



Temperature chart, Case 4. P, pneumothorax treatment: September 26, injected 350 c.c. of nitrogen gas; September 29, 425 c.c. of nitrogen gas; October 1, 650 c.c. of nitrogen gas; October 9, 575 c.c. of nitrogen gas; October 17, 575 c.c. of nitrogen gas; October 24, 400 c.c. of nitrogen gas.

Case 5 (1308). — D. C., aged 38. Admitted Aug. 6, 1913, with involvement scattered throughout the greater part of the left lung, moderate consolidation upper part of the right lung; severe cough, profuse sputum, tubercle bacilli present, temperature range 99.5 to 100. Pneumothorax treatment begun Sept. 2, 1913; owing to pleural adhesions only a partial collapse of the lung was obtained. The treatment was continued until November 18. For a while the temperature was somewhat improved, but owing to an acute exacerbation developing in the left lung, complicated by pleurisy with effusion, the treatment was discontinued.

Case 6 (1275).—A. H., aged 45. Admitted May 14, 1913, involvement throughout the greater part of right lung, infiltration top of left lung; cough severe, profuse sputum, tubercle bacilli present; temperature range 100 to 102. Pneumothorax treatment given July 23, 1913; only partial collapse obtained. Six injections were given in all, temperature range increasing from 102 to 103. Patient unimproved.

Case 7 (1166).—A. C., aged 20. Admitted Sept. 5, 1912, consolidation throughout greater part of right lung and lower part of left lung; moderate amount of sputum, tubercle bacilli present, troublesome cough, temperature range from 99.5 to 102. Pneumothorax treatment begun Oct. 25, 1912; temperature 100 in the afternoon. In all, eight refills were given, and while we obtained a good collapse of the right lung, and the temperature for a while was decidedly lower, the treatment was discontinued Jan. 9, 1913, owing to decided extension of the disease in the other lung. Patient discharged unimproved.

Case 8 (1274).—F. W., aged 45. Admitted May 13, 1913, involvement throughout the greater part of the left lung, cavity at top, right lung clear. Moderate amount of cough and expectoration, tubercle bacilli present. Temperature range from 100 to 101. Pneumothorax begun June 18, 1913. Sixteen refills were given in all and a fairly good collapse was obtained. Cough and expectoration lessened. Last treatment was given Dec. 1, 1913. Owing to the disease ment would not be justifiable in patients even though far advanced who are doing well under the usual therapeutic measures. Generally, basal lesions in the opposite lung are contraindications and are less favorable in the collapsed lung. Endocarditis and nephritis would lessen the chances of recovery in proportion to their severity. While dense pleural adhesions could not, strictly speaking, be considered contraindications, they are nevertheless the chief cause of a large percentage of failures.

TECHNIC

The Floyd-Robinson apparatus is the one used by us. It is very simple and easy to operate. It being determined to collapse a lung in a selected case, the patient is given beforehand one-eighth grain of morphin hypodermically for the first, rarely, for the subsequent injections.

Factors Which Should Be a Guide in Selecting the Point of Puncture.—An area is chosen as far away as possible from the original site of the disease, as here there are less likely to be found pleural adhesions. The physical signs are very often misleading. We endeavor to find an area where there is good lung resonance, good breathing, no adventitious sounds, preferably in the seventh or eighth interspace, scapular line, or at any point between the anterior axillary line and the scapular line. Efforts to find a free pleural space are often a failure, and frequent attempts have to be made in different places before a free space is found. We have often failed where by percussion and auscultation we had reason to believe we would be successful, and vice versa.

Position of the Patient.—This will necessarily vary according to the point of election. The patient lies on the side, with the lung to be collapsed uppermost. A pillow is placed in the axilla of the side on which the patient is reclining. This facilitates the widening of the intercostal space.

Preparation of the Skin.—After being properly sterilized, a small area of the skin is painted with tincture of iodin and the excess removed with alcohol.

Cocainization.—An all glass syringe is used, with a platinum needle just long enough (1 inch) to pass through the parietal pleura. We have found that 2 c.c. of a 0.25 per cent. novocain solution gives excellent results. The index and middle fingers of the left hand are placed on the upper border of the rib. A large sized wheal is made in the skin between the ribs. The tissues are then carefully cocainized, waiting until the structures in advance of the needle are thoroughly cocainized before advancing the needle farther. When the parietal layer of pleura is reached, the patient often feels a slight pricking sensation, and here we use the novocain solution freely. The structures from without inward offering resistance to the needle are as follows: the skin; external intercostal fascia, very dense; middle intercostal fascia, very little resistance; internal intercostal fascia and pleura, quite dense and generally perceptible resistance; when the pleura is thickened, marked resistance. A small puncture is now made through the epidermis and the dense external intercostal fascia with a cataract knife, and we are now ready to introduce the gas needle. The needle is held in the hollow of the right hand, between the thumb and index finger, and the tip of the index finger is pressed against the chest wall in order to have the needle under perfect control. With the gas needle we can readily determine the different layers of tissue through which it is passing, and it often passes through them with an audible snap.

The needle having pierced the external and middle intercostal fascia, we are now obliged to proceed cautiously as we approach the internal intercostal fascia and the costal pleura. The rubber tubing, having been previously connected with the needle, we now pull out the obturator and refer frequently to the manometer reading. When the needle rests against the costal pleura, a very slight oscillation can be seen, but by advancing the needle very slightly, if there are no pleural adhesions, a good free space may be observed, giving a reading, say from — 4 to — 10 cm., or — 6 to — 12 cm., actual reading. The negative reading is naturally greater during inspiration than expiration. If there are slight pleural adhesions, the reading may not be more than from — 2 to — 4 cm.

A suitable space having been found, we now close the cock leading to the manometer and slowly introduce 50 c.c. of nitrogen gas, the gas being warmed by placing the middle coils of rubber tubing in a basin of hot water; then shutting off the gas, we again consult the manometer carefully, and so on until the gas needed for the individual case is given. In new cases it is far better to inject a small amount of nitrogen gas, say from 300 to 500 c.c., leaving a negative end reading, then give refills every three to five days until gradually a total collapse of the lung is obtained. This overcomes the danger and discomfort caused by displacing the heart and other organs too rapidly, and by allowing the heart time to accommodate itself to its new position. A large needle is used for the initial injection, a smaller one for the refills.

DANGERS AND SEQUELAE

The following are some of the complications that might follow the induction of artificial pneumothorax: Pleurisy with effusion may occur in as high as 50 per cent. of the cases. The cause of this is not clear; some writers believe that it is due principally to chilling of the body, others to faulty technic, and still others to the mechanical irritation of the layers of the pleura, due to the foreign body, nitrogen gas. The fluid in a large percentage of the cases is found to contain tubercle bacilli. This complication, though rarely serious, is an annoying one. The fluid persists for a long time, but generally should not be removed unless causing disturbing symptoms; the fluid may then be withdrawn and nitrogen gas introduced to take its place. Tuberculous pyopneumothorax occurs in a small percentage of these effusions, but does not necessarily give a bad prognosis under the expectant treatment. Some instances of secondary infections have been reported, in which cases the outlook, unfortunately, must be regarded as very serious.

Shock: While numerous cases of shock have been reported in literature, and the real cause is still in doubt, this can probably be avoided by careful cocainization of the tissues and by the initial injection of morphin.

Gas Embolism: If the manometer is carefully consulted, and a good free oscillation is observed before any gas is introduced, this danger may be considered remote.

Emphysema: Emphysema, superficial or deep, may be encountered, but rarely produces any serious symptoms. The subcutaneous variety is due either to too great intrapleural pressure, or to the patient coughing during or soon after the operation, thereby forcing the nitrogen gas out of the pleural space, which becomes diffused along the subcutaneous tissue. The deep variety is undoubtedly due to excessive intrapleural pressure. Both varieties of emphysema generally pass off in from twelve hours to two or three days.

Puncture of the Lung: The puncture of the lung parenchyma, *followed by slight bleeding*, may occur, but generally does not cause any serious symptoms; spontaneous pneumothorax might ensue where no adhesions prevent.

Dilatation of the Heart: This is a serious complication, and is generally due to too great intrathoracic pressure. It is far better to be satisfied with allowing the end reading to remain at zero, rarely above + 4, and gradually to induce a pneumothorax and permit the heart to accommodate itself to the increased pleural pressure.

Pain more or less severe caused by breaking up of pleural adhesions may be mentioned among the complications. *Generally* in left-sided gas cases the apex of the heart is displaced to the right to a greater or less degree.

REPORT OF CASES

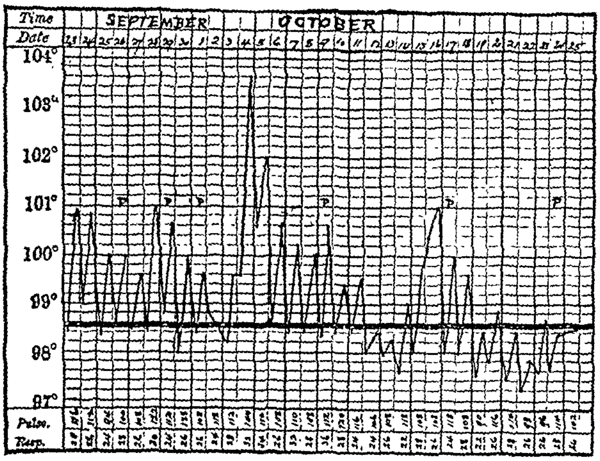
The following is a report of fifteen cases in which we were more or less successful, according to the degree of lung collapse.

CASE 1 (1198).—M. P., aged 24. Admitted Nov. 2, 1912, with marked consolidation and considerable moisture upper half left lung, slight infiltration right apex. Severe cough and profuse expectoration. Beginning Feb. 10, 1913, temperature range 101 to 102. Pneumothorax begun February 15, manometer reading —2, —5 cm., injected 325 c.c. of gas, end reading + 2, — 2. *Refills* were given at varying intervals until March 15, when treatment was discontinued on account of the resulting small space. Ten days after the first injection the temperature dropped to normal and remained practically so until April 1; temperature now ranged from 101 to 103, with signs of a large cavity developing at the top of the left lung, and patient was discharged May 10, 1913, unimproved.

CASE 2 (1324).—H. S., aged 20. Admitted Sept. 22, 1913, with marked consolidation upper half left lung, slight infiltration right apex; severe cough, profuse expectoration with bacilli present; temperature range 100 to 101.5. Gas treatment begun Oct. 17, 1913. Puncture was made in the ninth intercostal space, scapular line, manometer reading 3, —8. Injected 350 c.c. of nitrogen gas, end reading —1.5, —4. Nineteen refills were given in all, at intervals of a few days to one to two weeks, quantity of gas injected ranging from 300 to 600 c.c., and, from the physical findings, a good collapse was obtained. Four days after the treatment was begun the temperature dropped from the range of 100 to 101.5 to 99 to 100, cough improved, sputum lessened. One month after the initial injection, tuberculous enteritis developed, and while the symptoms referable to the lungs all improved, the patient lost flesh steadily and was discharged May 2 unimproved, probably because of the enteric complication.

CASE 3 (1335).—M. M., aged 18. Admitted Oct. 25, 1913, with foci through the greater part of the left lung, infiltration right apex. Moderate cough and sputum, tubercle bacilli present. February 1, temperature 100.5 in the afternoon; March 9, pneumothorax treatment given. Temperature dropped to normal after four days and remained so until date of discharge, *April 13, 1914. The gas was administered* six times, and a good collapse of the lung was obtained. Cough and expectoration lessened, but patient developed tuberculous enteritis and was discharged unimproved.

CASE 4 (1311).—I. B., aged 25. Admitted Aug. 16, 1912, with involvement throughout the greater part of the right lung, cavity at top, left lung clear; troublesome cough, profuse *expectoration, tubercle bacilli present, temperature ranging* from 100 to 101, in the afternoon, pulse and respiration in proportion. Pneumothorax was given Sept. 26, 1913, manometer reading —8, —13, injected 350 c.c. of nitrogen gas, end reading —3, —7. Temperature gradually returned to normal by October 20 and has remained so ever since. Thirty-three refills have been given in all. Patient has only a few spots of *mucoid sputum two or three times a month*, tubercle bacilli absent since March, 1914; gain in weight 23¼ pounds. This is a case in which an acute, progressive disease was arrested by compression of the lung. Patient is now doing work in the sanatorium and is clinically well. The temperature chart showing the result of the treatment is reproduced herewith.



Temperature chart, Case 4. P, pneumothorax treatment: September 26, injected 350 c.c. of nitrogen gas; September 29, 425 c.c. of nitrogen gas; October 1, 650 c.c. of nitrogen gas; October 9, 575 c.c. of nitrogen gas; October 17, 575 c.c. of nitrogen gas; October 24, 400 c.c. of nitrogen gas.

CASE 5 (1308). — D. C., aged 38. Admitted Aug. 6, 1913, with involvement scattered throughout the greater part of the left lung, moderate consolidation upper part of the right lung; severe cough, profuse sputum, tubercle bacilli present, temperature range 99.5 to 100. Pneumothorax treatment begun Sept. 2, 1913; *owing to* pleural adhesions only a partial collapse of the lung was obtained. The treatment was continued until November 18. For a while the temperature was somewhat improved, but owing to an acute exacerbation developing in the left lung, complicated by pleurisy with effusion, the *treatment was discontinued.*

CASE 6 (1275).—A. H., aged 45. Admitted May 14, 1913, involvement throughout the greater part of right lung, infiltration top of left lung; cough severe, profuse sputum, tubercle bacilli present; temperature range 100 to 102. Pneumothorax treatment given July 23, 1913; only partial collapse obtained. Six injections were given in all, temperature range increasing from 102 to 103. Patient unimproved.

CASE 7 (1166).—A. C., aged 20. Admitted Sept. 5, 1912, consolidation throughout greater part of right lung and lower part of left lung; moderate amount of sputum, tubercle bacilli present, troublesome cough, temperature range from 99.5 to 102. Pneumothorax treatment begun Oct. 25, 1912; temperature 100 in the afternoon. In all, eight refills were given, and while we obtained a good collapse of the right lung, and the temperature for a while was decidedly lower, the treatment was discontinued Jan. 9, 1913, owing to decided extension of the disease in the other lung. Patient discharged unimproved.

CASE 8 (1274).—F. W., aged 45. Admitted May 13, 1913, *involvement throughout the greater part of the left lung*, cavity at top, right lung clear. Moderate amount of cough and expectoration, tubercle bacilli present. Temperature range from 100 to 101. Pneumothorax begun June 18, 1913. Sixteen refills were given in all and a fairly good collapse was obtained. Cough and expectoration lessened. Last treatment was given Dec. 1, 1913. Owing to the disease developing in the right lung, patient was discharged unimproved.

Case 9 (1191).—C. M., aged 24. Admitted Oct. 14, 1912, consolidation upper part of left lung, infiltration throughout the rest of lung and a few indistinct râles throughout the right lung anteriorly; temperature range from 99.5 to 100; cough and sputum present, tubercle bacilli found. Pneumothorax treatment begun Dec. 3, 1912; two days following temperature rose to 102 in the afternoon; later dropped to practically normal, with an occasional rise to 99.5 to Feb. 22, 1913. Since that time practically normal temperature until May, 1913, when patient developed pleurisy with effusion, temperature 100 to 103, and the gas treatment, which had been given every two or three weeks, was now discontinued until July 13, 1913, when some of the fluid was removed and replaced with nitrogen gas. This procedure was repeated twice during August. Subcutaneous emphysema developed after one injection, causing some pain, but this entirely disappeared in three days. From July to Sept. 23, 1913, temperature of patient was normal. An extensive laryngeal tuberculosis which she had on admission disappeared. The last time this patient was heard from she was seemingly in good health and working.

Case 10 (1156).—L. B., aged 39. Admitted July 6, 1912, with consolidation throughout the greater part of the left lung, cavity at top, infiltration top of right lung, a few small râles after cough. Temperature 99.5 to 100, cough troublesome and sputum increasing. As the disease was steadily progressing in the left lung, pneumothorax was given, February 17, and a good collapse was obtained; twenty-seven injections were made in all. Patient developed pleurisy with effusion in June. Treatment consisted at times of removing some of the fluid and replacing with nitrogen gas. Shortly after the treatment was given the temperature dropped to normal, practically no cough, slight sputum, tubercle bacilli absent, signs at the top of the opposite lung improved. Patient gained 11¾ pounds and was discharged much improved; fluid still present at base of left lung.

Case 11 (1437).—B. S., aged 35. Admitted Aug. 26, 1914; left lung had previously been partially collapsed. Treatment was continued from September, 1914, to January, 1915. During residence patient had an occasional rise of temperature to 99.5; small area of infiltration which was found on admission at the base of right lung remained practically unchanged; slight cough and sputum present on admission disappeared. Discharged improved.

Case 12 (1307).—M. W., aged 25. Admitted Aug. 4, 1913, slight cough, no expectoration, slight infiltration left apex, right lung clear. Patient did fairly well until April, 1914, gaining 12 pounds. From this time the disease progressed steadily. Beginning Aug. 17, 1914, signs of softening, top of left lung, right clear, cough troublesome, profuse expectoration with tubercle bacilli present, temperature ranging from 100 to 103. Pneumothorax was begun August 18 and was repeated at intervals of a few days to from one to two weeks. A good collapse of the lung was obtained, cough improved, temperature ranging somewhat lower. In October, patient developed tuberculous enteritis, which grew steadily worse, and while the symptoms referable to the lungs improved considerably, patient lost weight steadily and was discharged March 9, 1915, unimproved.

Case 13 (1260).—M. P., aged 24. Admitted April 19, 1913, with an infiltration of the upper half of the left lung and right apex, moderate amount of sputum, tubercle bacilli present, temperature range from 99 to 99.5. Did fairly well until June, 1914. Pneumothorax treatment begun July 10, 1914; fairly good collapse obtained, nothing heard over left lung, except bronchial breathing and subcrepitant râles at apex. Eighteen refills have been given to date; cough has practically disappeared. Beginning with September, 1914, only one or two spots of mucoid sputum daily, tubercle bacilli not found, temperature normal. Patient is now at the sanatorium receiving the treatment every three to four weeks, and is clinically well.

Case 14 (1266).—R. H., aged 19. Patient was referred to us by Dr. Fred H. Heise, resident physician, Adirondack Cottage Sanatorium, Trudeau. The following is his report of the case while the patient was under his supervision: "Right lung clear, with the exception of slight changes in voice and breathing at apex; left lung showed infiltration to the third rib anteriorly and to ninth vertebral spine. It was decided to collapse the left lung owing to persistent hemoptysis, and treatment was begun Nov. 24, 1912. Refills were given at intervals of three to three and a half weeks, and two months later the patient had no symptoms and improved so much that she was allowed five minutes' exercise, which was gradually increased to one hour twice daily, when she was discharged from the sanatorium the latter part of April, 1913." Patient was admitted to Stony Wold Sanatorium May 1, 1913, and treatment was continued every three weeks. During residence here, patient had no symptoms and was discharged, Oct. 29, 1913, clinically well. She has been working ever since, and the last time we heard from her she was apparently well and still receiving the pneumothorax treatment.

Case 15 (1304).—R. S., aged 16. Admitted July 24, 1913. Right lung negative, left lung active infiltration upper half. Cough, profuse expectoration, tubercle bacilli present. Disease was steadily progressing in the left lung, with temperature ranging from 99.5 to 100. Pneumothorax treatment was begun Oct. 8, 1914, eleven refills in all being given. Two days after the initial injection temperature dropped to 99, with only an occasional rise to 99.5, practically no cough, slight expectoration, once or twice a week, tubercle bacilli absent. Patient was discharged March 20, 1915, much improved.

CONCLUSIONS

It is most gratifying that at last we have a rational treatment that can be used in the far-advanced cases. A comparatively few years ago symptomatic treatment, with the hope of temporary relief, was the only one given. The present status of artificial pneumothorax is that in a fair percentage of these hopeless cases we can offer either an arrest of the disease, or a chance of returning to good health. The procedure is, like any other operation, attended with slight dangers, but these are insignificant as contrasted with the fatal outcome if the disease is allowed to go on unchecked. The duration of treatment is one offering the greatest problem. It is impossible, of course, to determine whether the tuberculous foci in the collapsed lung have become entirely cicatrized, even though the patient is clinically well. It is far better to continue the treatment for an indefinite period, extending over years, than to discontinue the compression and discover after a few months that the disease is becoming active again, and when an attempt is made to readminister gas, that the layers of the pleura are densely adhered.

Elements of American Mortality.—Returns available for the United States for the registration area, which includes about 65 per cent. of the total population, show that the general death rate has fallen from 20.8 per 1,000 in 1890 to 14.1 in 1913. Throughout the period under observation the male rate has been in excess of the female rate, and in 1913 the rates were 15.0 for males and 13.1 for females. For the white population the mortality was 14.0 per 1,000, and for the colored 22.9. For white males the rate was 14.9, and for white females 13.1. For colored males the rate was 24.9, and for colored females 21.0. For certain principal causes the comparative death rates for the two sexes were as follows: tuberculosis of the lungs, males, 14.9, females, 12.0; pneumonia, males, 14.7, females, 12.6; accidents, males, 12.8, females, 4.0; urinary diseases, males, 10.8, females, 8.8; cancer, males, 5.8, females, 9.3; typhoid fever, males, 2.5, females, 1.7; suicides, males, 2.5, females, 0.8. The urban death rate for the registration area for the period 1908-1912 was 15.5 per 1,000, and the rural death rate was 12.9.

DIAGNOSTIC THESES IN PULMONARY TUBERCULOSIS

LAWRASON BROWN, M.D.
SARANAC LAKE, N. Y.

Since the time of Hippocrates, many medical aphorisms have been published, and as they convey in a concise and at times a clear manner the experience of the writer, they are often read. Such theses must include many well-known facts to which all subscribe, and their *raison d'être* lies in the fact that assent or dissent is at once forthcoming. For the beginner in work in pulmonary tuberculosis, succinct opinions on diagnosis are of great assistance.

DIAGNOSTIC THESES

1. An appearance of ruddy health does not exclude tuberculosis.

2. In any patient with constitut[illegible] matter of what he complains, the [illegible] culosis must be kept constantly in mind.

3. Prolonged and intimate exposure at any time of life, but especially in childhood, and in home or workshop or office, is vastly more important in diagnosis than "unassociated" or "noncontact" heredity.

4. Prolonged contact with tuberculosis may lead to infection, but debilitating conditions are necessary usually to cause this to develop into clinical tuberculosis.

5. Constitutional or general symptoms lead us to a diagnosis of tuberculosis, while the localizing symptoms point out the organs involved.

6. The history or presence of certain complications, as fistula-in-ano, pleurisy, dry or especially with effusion, adenitis, a discharging ear, coming on painlessly, are all strongly suggestive of tuberculosis.

7. Loss of color, prolonged exposure to tuberculous infection, especially in childhood, with a history of swollen glands at that time, the more recent subjection to debilitating conditions, the presence of unequivocal constitutional and localizing symptoms, with or without the aforementioned complications, demand a diagnosis of pulmonary tuberculosis even though no abnormal physical signs are present in the lungs.

8. *Your* patients, *your* friends, *your* family are as prone to contract and develop pulmonary tuberculosis as hundreds of others.

9. The importance of physical examination in the diagnosis of pulmonary tuberculosis has been overemphasized.

10. Symptoms are a better and more accurate guide to activity than physical signs.

11. Symptoms without physical signs demand treatment, while physical signs without symptoms require only careful watching.

12. Slight but persistent rise in temperature and increase in rapidity of pulse are often present early in the disease.

13. The usual weight of a patient who develops pulmonary tuberculosis is often 10 pounds below the normal weight for his height and age.

14. Failure to interpret rightly the significance of symptoms, to detect the presence of abnormal physical signs, can be condoned; but failure to ask for and examine the sputum repeatedly in any patient with chronic cough is inexcusable.

15. Absence of tubercle bacilli in the sputum means only that bronchial ulceration has not occurred.

16. Auscultation and inspection are the most important procedures in the detection of abnormal physical signs.

17. Inspection reveals localized retraction of the chest wall and limitations of the chest movement.

18. Auscultation is more important than inspection, and the detection of râles by the auscultation of the inspiration following cough is the most important procedure in the detection of physical signs of early pulmonary tuberculosis.

19. Changes in the relative lengths and intensity of the inspiration and expiration are valuable but less easy to detect.

20. The disease is practically always more extensive than the physical signs indicate.

21. Abnormal physical signs in one apex should be considered as due to pulmonary tuberculosis until proved not to be, while those at the base should be looked on as nontuberculous until definitely proved so.

22. The fluoroscope, the roentgenogram and stereoscopic plates may reveal and locate pathologic pulmonary changes to be detected by no other means.

23. When sputum is lacking, or when tubercle bacilli are absent on repeated examinations, the possibility of the presence of bronchiectasis, hyperthyroidism, syphilis and influenza, and more rarely pulmonary tumor and Hodgkin's disease, should be borne in mind.

24 No modification of the tuberculin tests as yet devised differentiates clearly clinical tuberculosis that demands vigorous treatment from nonclinical tuberculosis that requires only a God-fearing life.

25. It may be impossible to determine definitely the presence or absence of clinical tuberculosis.

MEASURES FOR PROMOTING THE NUTRITION IN THE PSYCHOSES *

SANGER BROWN, M.D.
CHICAGO

At a time when biochemistry and microscopy are achieving such brilliant results in demonstrating the etiology and pathology of disease, a discussion of time-honored methods of treatment may naturally be expected to provoke only a more or less modified interest. Nevertheless, I regard such a discussion as seasonable, and all the more so since the fascinations of science logically tend to diminish confidence in and thus lead to neglect of measures which, though their value may have been ever so amply attested by many years of experience, *in their inception* at least, were essentially empiric. *Not to be misunderstood*, I wish to express my most sincere respect and admiration for the efforts that are being put forth with a purpose of discovering a palpable cause of insanity, and hence rational plans of prevention and cure; pending such discovery, however, it is expedient to make the most of what we possess, even though it falls ever so far short of what we desire.

My purpose is to describe briefly certain measures for promoting the nutrition and the manner of their application in cases of insanity, as I commonly employ them in practice. No claim of novelty or originality is made.
